At the beginning of December, 1914, the first complete hospital unit was sent out under the French Red Cross, and was established in the Abbaye de Royaumont. Within easy distance of a large evacuating station the Abbaye, from its size and situation, proved to be an excellent site. Although within sound of the guns, its architectural beauty and the forest scenery in the neighbourhood made it an ideal spot in which the wounded soldier could forget for a time the horrors and discomfort of war. After inspection by the Service de Santé the hospital was opened on January 13th, 1915, as Hôpital Auxiliaire 301, fully equipped for the reception of surgical cases.

Dr. Agnes Savill has described the difficulties encountered in making the first *x*-ray installation. An *x*-ray room was fitted up close to the operating theatre and a developing room was contrived in a large cupboard with a fish-kettle as a cistern. In spite of this the developing was easily performed until there came a rush of work. Then a village plumber, who had known the abbey in the days of the nuns, found a cold water pipe in a cupboard on the first floor. This space was promptly fitted up as a developing room, but experience of the first months proved that it was possible to turn out good work without all the luxuries and conveniences to which students trained in a medical school are accustomed.

In a short time a bacteriological laboratory was added, a theatre, and an elaborate x-ray installation were equipped, and the number of beds was increased to 400. The cloisters lent themselves very well for the open-air treatment of wounds, and the large halls on the ground floor made it possible to wheel the beds out so that a large proportion of the cases could spend part of the day out of doors.

The medical staff included a surgeon-in-charge, five assistant surgeons, an anaesthetist, and a bacteriologist; there were thirty trained nurses, and about forty women orderlies, usually untrained volunteers who worked in the wards as probationers, helped in the kitchen, looked after stores, carried stretchers, and assisted in all the departments under trained heads.

The wounded were brought in from the military evacuating station by motor ambulances under the charge of women drivers. This is responsible work, for trains frequently arrive at night, the roads are by no means ideal, and during a rush the chauffeurs must work many hours without a break.

An x-ray car enables the radiologist to do radiographic work for those neighbouring hospitals which have no installation.

From the start the work of the Royaumont Hospital has been continuous, though in the early summer of 1916 the hospital was almost cleared in preparation for the attack on the Somme. The refectory was then arranged as a ward with 100 beds, and in a few hours, on July 2nd, was almost filled with seriously wounded cases.

In two years 2,527 patients had passed through the hospital and 2,859 operations had been performed, with a mortality of 48 (1.9 per cent.). Cases of almost every

form of treatment required. The factors enumerated as of importance in the production of gas gangrene were:

1. The proximity to contaminated soil. Wounds of the lower limb showed a mortality three times as great as those of the upper, though wounds of the upper were more frequent.

2. Shell wounds were six times as frequent in gas gangrene as in ordinary infected wounds.

3. The presence of an infected wad of clothing kept up infection.

4. The interval between the wound and the first surgical intervention; insignificant wounds if severely infected might cause fatal results if untreated. Early treatment was most important in the prevention of gas gangrene.

5. Vascular lesions were an important factor when due to injury; as a remedial measure, namely, ligature of great vessels, they were not important; twenty-two cases with vascular lesions were followed by gangrene in six only.

6. Sixty per cent. of gas-infected cases had fractures, and 71 per cent. of those of gas gangrene.

7. Joint injuries occurred in 13 per cent. of gas infections and in 20 per cent. of gas gangrene. They increased the gravity of cases, as damaged joints were difficult to immobilize without pressure.

8. Wounds of the calf, trunk, or hip-joint were specially dangerous.

9. Tissue injury had an important influence. Gas abscesses were frequently seen in gas infections at the site of subcutaneous injections or near simple fractures in the same case.

10. Intramuscular tension from within or without was a potent aid in the production of gangrene.

It was found that the flora of gas gangrene was usually multiple: *B. perfringens* was present in nearly every case, *B. sporogenes* in 41 cases, *Vibrio septique* in 6 cases (several fatal); *B. histolyticus*, *B. Hübner IX*, and

FIG. 2.—The Theatre.

type of severity were admitted, but when an attack was proceeding they generally included a percentage of cases of gas gangrene. In December, 1916, Miss Ivens, M.S., Médecin Chef of the hospital, read a paper before the Surgical Section of the Royal Society of Medicine, in which she dealt with cases of anaerobic wound infections which had occurred in the hospital. She presented an analysis of 464 cases of gas infection, of which 107 were clinically gas gangrene. Attention was drawn to the importance of complete bacteriological study and the careful examination of the x-ray plates, which, in the majority of cases, showed the situation of gas bubbles or streaks according to the species of microbe present, thus affording extremely valuable aid in a decision as to the

FIG. 3.—X-ray car with tent.

B. oedematis were all reported, but less frequently. Streptococci of a virulent type were present in 59 cases, and added to the gravity of the infection. Tetanus occurred in 15 cases; and was demonstrated bacteriologically in 7. Marked and latent forms of tetanus were described. Intrathecal administration of serum, 30 c.cm. at a dose, together with subcutaneous injections up to 30 or 40 c.cm. a day, proved successful. Seven clinical forms of gas gangrene were noted: (1) Classic form (Weinberg); (2) toxic or oedematous type; (3) mixed forms; (4) local gas abscess; (5) superficial and deep-seated gas phlegmon; (6) chronic and latent infections; (7) gas septicaemia or pyaemia.

Of 464 cases of gas infection 42 were fatal, 25 dying

from gas gangrene, 4 with tetanus, and the remainder with severe fractures, brain or abdominal injuries.

Amputation was considered necessary in advanced cases of gangrene; it was performed 65 times, with 48 recoveries, by the open method with lateral incisions. When gangrene was limited to groups of muscles or joints, excision was performed—41 times, with 33 recoveries. Hypertonic salt treatment alone was found to be unsuccessful, but combined with 2½ per cent. carbolic acid had given good results. Other methods used, such as continuous irrigation with eusol, Dakin's solution, or normal saline, apparently gave the same results. Ten cases of very severe gas gangrene were treated by antiserum for *B. perfringens*, *B. oedematiens* and *Vibrio septique*. In five cases (one being an instance of septicaemia with triple anaerobic infection) the results were successful. The fatal cases were already septicaemic before serum was given. There was distinct evidence that its curative use might be advantageous and probably its prophylactic use even more valuable.

In the work of the hospital bone injuries were common, over 900 fractures being admitted.

The operations performed included 1,057 for shell and grenade wounds, 264 for bullet wounds, 68 amputations and 59 reamputations, 78 joint operations, 176 for radical cure of hernia, 41 for appendicectomy, and 60 nerve and tendon operations. In addition, 200 civilians from the district were admitted for operative treatment.

When the climate allowed, the sun was found to be a valuable aid in the treatment of wounds, which were exposed, with a thin layer of gauze to keep away flies.

During the two years 3,612 x-ray photographs were taken, including a special series showing the presence of gas in the tissues, a subject on which Dr. Agnes Savill made a communication to the Royal Society of Medicine in October, 1916.

Work in Serbia.

The Scottish Women's Hospitals sent out their first unit to Serbia in January, 1915, just after the Austrians had been driven over the Serbian frontier, leaving thousands of sick and wounded. Typhus of a virulent type was raging and the mortality was very high.

The unit went to Kragujevatz, the arsenal of Serbia, where it took charge of 570 beds. The first hospital was prepared in about forty-eight hours. The patients were in a miserable condition, many suffering from septic wounds and bedsores. They were found in all available buildings in the town shivering and verminous. To deal with the large numbers Dr. Eleanor Soltan in a short time opened other buildings with fresh equipment sent from Scotland. At Valjevo 70,000 typhus cases were lying unattended; some were sent at once to Kragujevatz, and Dr. Alice Hutchinson was sent with another unit to open a camp hospital at Valjevo. On its way out the unit stopped for a short time at Malta to nurse British wounded from the Dardanelles. Next Dr. Elsie Inglis arrived in Serbia and opened two additional hospitals, one at Mladanovatz and the other at Lazarovatz. The former hospital was named the Neil Fraser Memorial, after a member of the first unit who had died of typhus. This hospital was under the charge of Dr. Beatrice Macgregor, and was continuously full. The hospital at Lazarovatz, housed in inns and dwelling-houses of the village, was able to accommodate 400 patients.

In an account of some of the medical work done during her ten months in Serbia, Dr. Chesney has reported that 100 out of the 300 officers of the Serbian army medical service died from the fever, and that the Scottish Women's Hospital unit, to which she was attached at Kragujevatz, also suffered severely. Two buildings were taken over at

Kragujevatz, so that cases of recurrent fever could be separated from typhus, but in a short time the wards contained nothing but typhus. The windows were kept open, and only one patient was allowed in each bed. The patients were washed, and lice hunted out of every hiding place; but fleas were ineradicable. The bathing arrangements and water heating apparatus were rough but efficient, though fuel was difficult to obtain. The sanitary arrangements were primitive; they consisted of a room with a small hole in a wooden box over a cesspool, and when this was filled up another small room was taken and another cesspool constructed. The cesspools were emptied by suction pumps and carts at intervals. Kragujevatz has normally a population of 10,000, but during the war there were about 20,000, and only five sanitary carts could be allowed for the town. With all its disadvantages the results in the hospital compared favourably with most of those in Skopliji and Banja, where buildings and sanitation were good. Each ward had two English sisters, and a Serbian and two Austrian orderlies. The Austrians made good nurses, and the Serbians preferred their ministrations. They were decent, friendly, and hard working. The sisters maintained discipline with ease by means of a sign language.

Typhus was at its height in February. It was of a very severe type and the death-rate extremely high. Nearly all cases were in the sixth or seventh day of illness when

admitted, with the rash well out. Strong patients seemed to suffer most severely; the delirium was more severe, and when this persisted the case was nearly always fatal. The Austrian prisoners often died from heart failure just before the crisis; the majority of deaths were just at the crisis. In the Serbian hospitals the most common complication was gangrene of a moist type, but Dr. Chesney had no such cases, although numb and painful feet occurred not uncommonly. Eleven bullock wagons were sent to the surgical hospital laden with patients suffering from post-typhus gangrene, in an appalling condition from want of nursing.

Post-typhus pneumonia was fairly common. The patients responded to good nursing, and the death-rate at this 6th Reserve Hospital was about 16 per cent., which was very low considering the violence of the epidemic.

The precautions against lice taken by the staff were to wear high boots, and to protect the wrist and neck with bandages rubbed with naphthalene. With the advent of summer typhus rapidly died down, the cases became milder, and finally ceased. Recurrent fever followed the same course, and during the summer, except for diphtheria, Serbia was quite healthy.

The Scottish Women's Hospital units worked in Serbia through the summer of 1915 until the advance of the Austro-German army swept them back. First, the Mladanovatz unit, which had treated more than 1,400 cases, had to fall back on Kragujevatz. Next, the Valjevo hospital had to retreat west to Vrnjatichka—Banja, where the members were made prisoners of war and taken to Hungary. The Lazarovatz unit retired to Kurjevatz.

Sir Ralph Paget, British Commissioner, arranged for those who wished to retreat into Montenegro. They endured terrible hardships travelling over snow-capped mountains 7,000 feet high, with food at famine prices, and shelter often not procurable, but with one exception all reached the coast in safety. In Kragujevatz during the first three months of the enemy occupation the care of a large number of Serbian wounded was given over to the Scottish Women's Hospital, and as there was great overcrowding an outbreak of typhus was feared, and an infectious hospital was organized with difficulty, as the Germans would give no other building.

FIG. 4.—Convalescent French soldiers on the terrace.

Bathing arrangements were improvised and disinfectors set going. The sanitation was deplorable, and it was necessary to empty the overflowing cesspools, to build incinerators, and to clean incessantly. Thousands of Serbian prisoners taken in the south passed through Kurfevatz miserably underfed. Their sufferings from hunger and exposure were very great. Hospital rations were meagre, and any extra articles, such as milk and eggs, were liable to be seized at the hospital gates by the Austrians. On February 9th the hospital was evacuated. The greater number of patients had been removed to Hungary, and the few remaining, badly wounded, were taken into Austrian hospitals. On February 11th, 1916, the entire hospital staff was sent north under an Austrian guard. In Vienna the Austrian Embassy took charge of them, and they were finally sent home through Zurich.

Work in Salonica.

In May, 1915, the second French hospital under Dr. Mellroy was opened at Troyes. It was established in tents, and at the end of the summer was sent with the French Expeditionary Force to the Balkans. For a month it was stationed at Ghegeli, and cases were received from the front, which was about fifteen miles away. Orders were then given to evacuate, and the hospital retreated to Salonica, where it opened as a tent hospital on January 1st, 1916, on a stretch of flat ground near the sea, overlooking the bay of Salonica. The medical staff consisted of five women doctors and a radiologist. The climate of Salonica was found very trying, and there was a considerable amount of sickness among the staff during the hot season, when the work was heaviest, 1,000 patients being admitted during July and August with dysentery, malaria, colic, diarrhoea, and jaundice. In October, when active hostilities began again, the hospital was used for wounded. The x-ray department treated a considerable number of cases with high frequency, electrical massage, hot air, light and ionization, under the direction of Miss Edith Stoney; cases were sent also from other hospitals for treatment. During the year 3,045 patients were admitted.

Work in Corsica.

Some of the Scottish women who had been in the Serbian retreat in December, 1915, appalled by the sufferings of the Serbians, undertook, with the approval of the French Government, the provision of medical care for the Serbian refugees in Corsica, and looked after them during their transport from Salonica to Corsica.

Dr. Blair landed in Ajaccio with the first transport full of Serbian refugees on Christmas eve, 1915, and took medical charge of the Serbian colony there. The refugees on the island at one time numbered 6,000. The first Serbs to arrive were from Southern Serbia, some civil officers and their wives and families, some peasants, but all at that time equally destitute, as they had fled before the Bulgarians, leaving everything behind them, and had suffered great privations. The maternity work started before the refugees reached Ajaccio, for a child was born on the first transport. There was a considerable amount of illness among the refugees, the result of exposure, privation, and exhaustion, and there was ever present the possibility of infectious disease. A suitable building was turned into a hospital, which was soon filled with patients, as, in addition to all the serious cases from the refugee colony, numbers of young recruits arrived from Corfu. They had been in the retreat through Montenegro and

Albania. The condition of these starving boys was most pitiable, and the most devoted nursing was not always successful in restoring them to health after the privations they had endured. Tuberculosis was extremely common. The most pathetic group of all to arrive were the school boys and students, who from 11 years upwards were marched to the Adriatic lest they should fall into the hands of the enemy; several thousands died by the way, thousands more after reaching the base, so many that the isle where they were quartered came to be known as L'Ile des Morts. The boys who recovered in the hospital were sent first to Great Britain and later to France.

The medical service for the Serbs consists of the main Scottish Women's Hospital at Ajaccio, the branch hospital for isolation (the Lazaret), and out-patient dispensaries at the refugee houses.

During the autumn of 1916 the hospital began to receive discharged incapacitated soldiers. It has over eighty beds occupied and is equipped with a theatre, pathological laboratory, and an x-ray installation. There is an open-air department for phthisis, and sun baths are an important part of the treatment. More than 2,000 patients were treated at Ajaccio alone. The Serbs were found to be extraordinarily interesting and grateful patients, and very much endeared themselves to their British nurses.

In the autumn of 1916 the second Serbian army was mobilized and re-equipped at Corfu. The Scottish Women's Hospital received an invitation to send out a

unit with it, and Dr. Agnes Bennett went to Salonica in charge of a well equipped hospital of 200 beds. The movements of the unit, which was attached to the Serbian army, were facilitated by the possession of motor transport sufficient not only for the wounded but for the staff. The hospital was first located near Salonica. Later on it

was moved to Ostrovo. The bad roads and heavy hill climbing made the transport difficult and dangerous. This hospital received many wounded from the Serbian army during its advance and proved of the greatest value to it. When the army moved forward a small outpost station was sent ahead to enable the most serious cases to be looked after for a few days before being transported over the bad roads. Mrs. Harley, sister of Lord French, who was killed recently in Monastir, was in charge of the transport column.

Work in Russia.

Another unit was sent out through Russia for the 1st Serbian Division of the Russian army in the Dobrudja. It was in charge of Dr. Elsie Inglis and Dr. Lilian Chesney, and started work in October, 1916, at Mejidia, where the barracks were converted into a hospital. About 300 patients were received during the eighteen days of its existence. Owing to the rapid advance of the Bulgars, it had then to be evacuated.

Meanwhile a second hospital had been established at Boulboulmick, consisting of three hospital tents and a dressing tent: after being occupied for a fortnight, it, too, had to retreat to a village near Mejidia. The final retreat was slow and arduous, and great hardships were suffered. The hospital equipment was transported through Cernavode by stages to Ismail and Galatz, and ultimately into Russia, only a motor kitchen and ambulance being lost. Dr. Inglis established dressing stations at Harsova and Braila and found many wounded at the latter place. The unit, when last heard of, was at Bessarabia, across the Russian frontier.

FIG. 5.—Scottish Women's Hospital for Serbian refugees in Corsica.

Work under the British War Office.

On leaving Paris Dr. Garrett Anderson and part of her staff did good work for some months at Wimereux in association with the R.A.M.C. It was then arranged by the Director-General, Sir Alfred Keogh, that they should organize a military hospital at Endell Street Workhouse Infirmary, London, which they have since conducted with great efficiency. Some results of experience gained there in the treatment of septic wounds have been published by Dr. Garrett Anderson; a first paper, written in conjunction with Miss Chambers, M.D., and Miss Lacey, B.Sc., was specially concerned with the use of salicylic acid. Basing themselves on the study of 1,000 cases they expressed the opinion that salicylic acid applied in a suitable form often saved cases when other methods failed, and was particularly useful when dressings could not be repeated at frequent intervals. They advised that in all cases in which recovery was delayed and the effect of the treatment doubtful it should be controlled by making repeated cultures from the wound surfaces. Drs. Garrett Anderson and Helen Chambers have since reported the results of a careful study of the paste (B.I.P.) recommended by Professor Rutherford Morison, which consists of bismuth subnitrate (1 oz.), iodoform (2 oz.), and paraffin sufficient to make a paste of the consistency of soft butter. The patient is anaesthetized, all gangrenous and necrosed tissue cut away, the wound thoroughly cleansed and swabbed out with rectified spirit, and a small portion of the paste vigorously rubbed into the tissues. As both the constituents are toxic not more than two grams should be used, but subject to this precaution the risk of toxic absorption was found to be negligible. A little of the paste is left at the bottom of the wound, which in many cases is closed with interrupted stitches, and dressed with gauze wrung out in spirit. No further dressing is required for seven to fourteen days; this is a great advantage in cases of compound fracture, as is also the fact that drainage tubes are not required. The paste maintains a continuous antiseptic action in the wound. It acts as a lymphagogue, producing a free exudation of serum which washes the wound from within outwards; it does not prevent the escape of discharges; granulation tissue grows freely in contact with it; drainage tubes and gauze drains are unnecessary; septic wounds heal nearly as rapidly as non-infected wounds; and bone union is rapid and the tendency to form sequestra slight.

Of 97 cases of compound fracture, 51.57 per cent. were completely healed within two and a half months of being wounded. Of 62 cases treated to a conclusion, 50 had healed, 4 had sinuses, and 8 superficial wounds. Of the whole series of cases treated, 6 complicated with suppurating joints required amputation after being treated with the paste, but in all extensive infection had occurred before they came under the treatment, and examination of the amputated limb showed that sepsis had subsided in the area to which the paste had been applied, but had spread extensively, so that the paste had not reached the whole of the infected area. Secondary haemorrhage occurred only in one of 400 cases. No case of gas gangrene or tetanus developed under the treatment, although anaerobes were grown from many of the wounds, and from some of them the tetanus bacillus; how much of the favourable results should be attributed to the injection of antitetanic serum, which every patient receives, could not certainly be stated. As compared with the Carrel-Dakin treatment, the object of treatment by B.I.P. is to use a less powerful antiseptic of feeble solubility, which keeps up a continuous action in the depths of the wound without requiring to be renewed for days or even weeks. A bacteriological and chemical examination carried out by Dr. Helen Chambers and J. N. Goldsmith, M.Sc., led to the conclusion that the bactericidal action of B.I.P. is due to the free iodine liberated from the oxidation of iodoform and by the nitric acid formed by the hydrolysis of bismuth subnitrate. The conclusion is that the chief reaction is the continued liberation of small quantities of iodine from a mixture practically insoluble in saline governed by the oxygen supplied from the air or from arterial blood. Cultures taken from open wounds under treatment by B.I.P. showed that they were not bacteriologically sterile, but that there was a reduction in the number of bacteria, which were not able to proliferate freely, and the wounds healed as if surgically clean. Most of the cases under this treatment excreted products of the decomposition of iodoform to a varying

extent, and the general effects of iodine absorption may have some bearing on the results.

PHYSICAL TREATMENT OF DISABLED SOLDIERS.

The problem of what should be done for soldiers suffering from results of injuries of joints and nerves and unfit to return to duty or to engage in any industry, but capable of cure or great improvement under suitable treatment, began to press for attention early in the war, and before long became one of great magnitude. At first the men were given extended leave at home, and were treated in out-patient departments or in special centres. One such centre for massage and electricity, promoted by Mr. and Mrs. Almeric Paget in London, was organized by Miss F. Barrie Lambert, M.B., with the help of the Hon. Essex French, daughter of Field-Marshal French. The circumstances under which many of the men were living militated against their recovery, and after inspecting the London centre the Director-General took steps to extend and systematize the treatment. The first great medical convalescent camp was established at Eastbourne, and subsequently command dépôts were added. Dr. Lambert was appointed medical officer in charge of a large mechano-therapeutic department at Eastbourne, where there was an electric installation furnishing galvanic, faradic, and combined currents, a plentiful supply of local radiant heat, and Schnee baths and vibrators. Dr. Lambert insisted on the importance of keeping the apparatus as simple as possible. In an article published last November she said that at the outset, though a fair number of masseuses and teachers of remedial gymnastics were available the supply of electricians was very limited, but that this difficulty had been got over by forming a staff of masseuses in squads, with in charge of each a skilled electrician who was responsible for the work and tuition of the other members. The plan proved satisfactory and was afterwards adopted in convalescent camps at Epsom and Dartford, so that when, some six months later, the command dépôts were started there was a nucleus of experienced and practical electricians to draw upon. The masseuse employed in military work is required to have not less than six months' training, and either to hold the certificate of the Incorporated Society of Trained Masseuses—as 90 per cent. of them do—or to satisfy the board of examiners set up by the War Office. The Eastbourne camp is large; there are 3,000 patients, and the visits to the electrical department vary between 600 and 800 daily. At Dartford camp are 1,200 patients, and from 150 to 200 electrical treatments are given daily. At Epsom, with 4,000 patients, from 500 to 700 are treated daily. Both these camps have been fitted, under the direction of Dr. Lambert, with apparatus similar to that installed at Eastbourne. Later on two other camps were established in the North of England, and there is a similar camp in Ireland, at Randalstown, and one having the same general purpose at Tipperary. It was found that after six months or so in these camps there was a residue of men who, though susceptible to cure, would require a much longer period of treatment—anything from four to six months; for their benefit command dépôts were established. In them convalescent soldiers belonging to particular commands are grouped. The cases are necessarily of a chronic type, and are subject to periodical inspection by medical boards, when men found to be incapable of further military service are discharged and become entitled to a pension. All cases in which it is thought that further improvement may be obtained by surgical interference are examined periodically by the Inspector of Orthopaedics or his representative. The men as they arrive at the command dépôts are drafted into one of five or six groups. In the first group are men who are practically fit but require final hardening by drill, route marching, and so on. In the second group the men receive physical drill, and are encouraged to take part in general sports. In the third group the men have light physical training and work. In the fourth group, consisting mostly of medical cases, the men have light physical training. The fifth group comprises the larger proportion of the cases which require massage, such as stiff joints, trench feet, and nerve injuries. The sixth group comprises cases of shell shock or men so gravely injured that they can only take light exercise and be trained in special movements to improve co-ordination. The average length of time for which a man remains in each dépôt is from two and a half to

three months, by which time he will reach Group I, and after going through the process of hardening will be fit to be transferred to army category A, B, or C.

Dr. Lambert considers that the system of convalescent camps and command dépôts is working very well, that massage is well and intelligently administered, and that the system of training by medical gymnasts is preferable to the use of Zander or other forms of mechanical apparatus.

Finally, it is to be noted that the number of men passed through and restored to health is very large; the number undergoing massage, electricity, and special exercise treatment in the command dépôts at one date in September was 8,262, and the total number of men who had then passed through the dépôts was 127,132.

THE ALLEGED PERILS OF URIC ACID.

BY

J. B. BERKART, M.D., M.R.C.P.,

LATE PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR
DISEASES OF THE CHEST.

THE public are, through the medium of the daily press, persistently reminded of the perils to which they are exposed from uric acid, but are at the same time confidently promised a safe escape from their dangers by the use of the remedies which the enterprising dealers recommend for that purpose. As all this is merely the usual exploitation of medical opinions which are still unsettled, it is advisable, therefore, to review briefly the alleged facts upon which it is based.

When deposits of uric acid were detected in the joints which had previously been the seats of painful inflammatory swellings, that substance was at once assumed to be the cause of gout; and not only of the typical and so-called regular manifestations of that disease, but also of all functional derangements and anatomical lesions which precede, accompany, and follow that peculiar affection of the joints. This view has gained general and speedy acceptance owing to a favourable concurrence of circumstances. There was the belief, which for centuries has been held—a belief so implicit that from its inception to this day it has never been questioned—that gout is essentially the consequence of excesses in eating and drinking, or of indulgence in particular articles of diet; and as uric acid was supposed to be an imperfect form of urea there was *prima facie* evidence of its causality. Not the less influential was the disappointment of practitioners who had long since turned away from the wranglings of the humoralists and solidists. Neither the shadowy product of a faulty distillation nor the mysterious influence of the nervous system could satisfy their longing after a clearer insight into the nature of the process with which they had to deal. The remedial measures, which they could plan only upon some speculative opinion, persistently failed. Their failures were disheartening to everybody concerned, and continued to be the subject of general derision as they had been at the time of the Satirists of old. But now there was a prospect of a change for the better. Here was a definite chemical body which as a derivative from food not only confirmed a doctrine held from the remotest antiquity, but encouraged the hope that if its formation could not altogether be avoided its consequences might at least be effectually averted.

Uric acid was thus with one accord admitted as the specific cause of gout; and though recently other substances have been suggested instead of it, it has hitherto lost none of the hold which it had gained at the moment of its discovery as a constituent of tophaceous deposits.

Nothing, however, was known how that peculiar substance obtained and how it exerted its alleged morbid action, for though presumably a toxic agent by virtue of its being an excrementitious substance, it was impossible to overlook the fact that it was invariably formed in the course of normal metabolism, and generally discharged without producing any disturbance. It was obvious therefore that there were here peculiar circumstances which led to its conversion into an irritant and to its deposition into the joints.

The fundamental doctrine supplied the key to the solution of the problem. Excesses in eating and drinking, it was argued, being the primary cause of the disease, it

followed that their product would be correspondingly large, and such a mass of effete matter would be enough to account for all the symptoms of gout. Thus the uric acid would contaminate the blood; and if it happened, as it often did, that other acids were generated within or introduced from without, they would render it insoluble. To avert the serious consequences that would ensue from the presence of that impurity the system made efforts to get rid of it, and in favourable circumstances succeeded in doing so by depositing it into the articular cartilages as being parts of no great importance for the preservation of life.

Since this theory was advanced it has been found that uric acid is derived not only from food, but also from the disintegration of the nuclei of the tissues. Whether its origin is endogenous or exogenous, even the largest quantities that may be formed are excreted without any concomitant derangement so long as the renal filter is intact, and whatever the disturbances associated with its imperfect elimination they are not produced by it. All the symptoms that occur in these circumstances are co-ordinate phenomena, and are due to some pathological changes in the kidneys which lead to a retention not only of uric acid but also of urea, of water, and of other effete substances. That such retention is not indifferent to the organism need hardly be insisted upon, but that uric acid is the sole, or even the most potent, element in the causation of the ensuing consequences is a purely gratuitous assumption.

Nothing has been definitely ascertained on this subject, although an over-production of uric acid in gout has been readily assumed. The current view on that point is merely an inference from the fundamental doctrine upon which the pathology of the disease has been constructed. Brugsch, however, holds as the result of his researches that uric acid is formed here in an abnormally small quantity—so small, indeed, that the presumably healthy kidneys are not sufficiently stimulated thereby to effect its removal. He alleges that it is retained in the blood and allowed gradually to accumulate there until it has reached an amount sufficient to break the renal barrier.

Nor is there the slightest evidence of any deficiency of alkalis in the blood, whereby uric acid is rendered insoluble, and thus becomes an impurity of which the organism can only rid itself by depositing it into the joints. Numerous hypotheses have been advanced to account for this supposed conversion, but none of them has been confirmed by actual examination. All inquiries into this subject have shown that there is no deficiency of alkalis, and that uric acid is perfectly soluble even in blood which is saturated with it. The statement of one writer that in his own case he felt, on the consumption of a few drops of an acid, the uric acid immediately rushing into his big toe, stands hitherto as an isolated experience.

Just as there is no foundation for the assumption of the several stages previously referred to which are said to lead ultimately to a deposition of urates, so there is none for the hypothesis that they, in the form of crystals, exert pathogenic influence. Whether they act in the typical attack of gout as mechanical irritants, as some maintain, or as toxic agents, as others hold—in either case it would be necessary that, being the alleged causes, their presence must precede the appearance of their consequences. But though the process takes place in the closed cavity of the joint, and is thus not accessible to direct inspection, yet the conclusion is fully justified that it is not different from what is observable on the surface. Thus Sir Alfred Garrod described the formation of an inflammatory tophus of the ear as starting with a vesicle of clear contents, in which the microscope showed a few uratic crystals. Gradually, when the serum was absorbed, the exudation became inspissated and opaque, the uratic crystals were then more numerous, and when all the fluid was removed the tophus remained. When there is occasion to examine such a tophus anatomically it will be found that there were initial changes either in the subcutaneous tissues or in the cartilage of the ear, or in both.

Not infrequently, however, urates are found on *post-mortem* examination of joints, in which their deposition was never attended by inflammatory or other symptoms, notwithstanding Sir Alfred Garrod's opinion that this cannot take place without producing some twinges. Commonly tophi of very large size are formed on the fingers without the least sign of any inflammatory

reaction, which appears only when the matrix in which the urates are deposited has begun to soften.

But as the term "gout" is generally used, both in theory and in practice, it is applied to all kinds of functional derangements and organic lesions, which are then described as visceral or irregular gout, and are supposed to be due to uric acid in the blood. Oftener than not that substance is not then found where it is supposed to exist. If it happens to be present, there is not the least evidence that any of those symptoms are produced by it, as it is met with in the ascitic, the pericardial, and the pleuritic effusions in connexion with such various diseases as valvular lesions of the heart, tuberculosis of the lungs, the pleura, and the peritoneum, with or without amyloid degeneration of the kidneys or the spleen; in acute pneumonia, in cirrhosis of the lungs and in pneumothorax; in marasmus due to stenosis of the pylorus due to a cicatrix of a gastric ulcer; in cirrhosis and cancer of the liver; in chronic interstitial and chronic parenchymatous nephritis; in amyloid degeneration of the kidneys; in pernicious anaemia; in chronic lead poisoning; in the contents of ovarian cysts; in hydrocele fluid, and in the ichor of gangrene of the lower extremities. On the inflamed or obsolete tissues, into which such transudations or effusions may have taken place, the uric acid may crystallize out of its solutions, and generally does so with the receding tide, but no one will seriously maintain that it is the cause of those various lesions. Uric crystals never occur in the circulating fluid; their deposition is an epiphenomenon, and is observed only in joints in which the cartilage was inflamed or has undergone amyloid degeneration or other changes; in the tissues of a degenerating cutaneous tophus; upon an atheromatous intima of the aorta; upon inflamed meninges; upon ulcers of the rectal mucous membrane, and within the corpora cavernosa of the penis, if they contain decayed or decaying matter.

Thus the clinical data afford no proof whatever of any pathogenic property of uric acid. Nor do the results of experimental inquiries. Subcutaneous injections of that substance into rabbits, and occasionally into guinea-pigs and dogs, have in no case produced a gouty inflammation of a joint or a tendon; they have led merely to deposits in the skin outwardly resembling tophi; but even that effect was obtained only by quantities thirty times as large as occur in man. Van Loghem introduced uratic crystals into the peritoneum of animals, and with the exception of a slight exudation of leucocytes, as may well be expected from the presence of such foreign bodies, he saw no deposits of crystals in the liver nor inflammatory reaction of its tissue. Leber, therefore, holds that only in considerable concentration does uric acid exhibit a very slight tendency to cause inflammation. Ibrahim, on the other hand, injected into himself a solution of 6 grains of uric acid with 9 grains of piperazin in 2 oz. of distilled water. The injection was very painful at the time, and continued to be so for hours or days; but the tissues, though hard and infiltrated, showed no sign of any nutritive changes. Freudweiler, however, alleges that he produced tophi which became inflamed; if so, these results are different from what takes place in the human subject, in whom the tophi generally remain an inert mass until the matrix softens. Whether he carried out his experiments with all necessary precautions does not appear from his reports of them.

In view of these facts, many clinical observers deny the causality of uric acid in gout and hold that the materies morbi is here a particular poison the nature of which is unknown. They make this unwarranted assumption because they hold that the gouty process takes place in previously healthy tissues.

There is consequently no indication for an exhibition of a uric acid solvent, because that substance is readily soluble in the tissue juices and is not the cause of the symptoms observed. Even if those alleged solvents served to remove all the uric acid from the blood, even then the patient would not be benefited thereby; for in the experience of His an intense treatment with radium completely drove out all uric acid from the blood, yet the gouty attacks returned with the same frequency and the same intensity as before. Moreover, such of the alleged solvents of uric acid which contain salts of soda have the undesirable consequence of favouring a deposition of uratic crystals.

Not only is the use of the pretended remedies to cure

the various functional derangements and organic lesions which are wrongly attributed to uric acid recommended upon a baseless hypothesis, but it is mischievous also, because it allures the unwary sufferer by specious advertisements of its effectiveness to have recourse to it and continue with it until its failure is evident. Thus valuable time is lost before he submits himself to rational treatment while there is still a reasonable prospect of satisfactorily coping with his disease.

ACETOZONE AS A GENERAL SURGICAL ANTISEPTIC.

BY

G. GORE-GILLON, LIEUT.-COLONEL R.A.M.C.,

CONSULTING SURGEON TO THE AUCKLAND HOSPITAL, NEW ZEALAND,
AND

R. T. HEWLETT, M.D., F.R.C.P.,

PROFESSOR OF BACTERIOLOGY, KING'S COLLEGE, UNIVERSITY OF LONDON.

The important properties of an ideal antiseptic appear to be (vide Browning and others, *BRITISH MEDICAL JOURNAL*, January 20th, 1917) that it has (1) great potency against all micro-organisms in presence of protein material, as serum, etc.; no deleterious effect on phagocytosis; (3) is innocuous to the tissues; has (4) a stimulating effect on connective tissue cells, so that it promotes healthy granulations; and is not toxic.

In benzoyl-acetyl-peroxide we have a preparation that fulfils these conditions. After previous experience of this substance in my surgical wards, I introduced it into this country in May, 1915, and have used it extensively in military hospitals since then as an antiseptic solution in the treatment of septic wounds. Its formula is $C_6H_5CO.O.O.COCH_3$, and it is known as acetozone. It has been used for years as an intestinal antiseptic in enteric fever and mucous colitis, and as a throat spray.

It may be used cold as a bath: (a) containing 5 grains to the pint (the cost is 8d. a gallon at army prices, and plenty of it is available); (b) or as a 7-grain solution with one-third hot water added. Its action is very rapid; unhealed amputation stumps heal quickly if put into a bath of this solution for half an hour daily, and dressed afterwards with dressings of sterile lint or gauze soaked in the 10-grain solution.

I have seen numerous cases of septic wounds which have resisted all other treatment for four or five months heal up in three weeks by this method.

It can be applied to deep wounds by Carrel-Dakin tubes, by the bath method, or in a waterproof bag, or by wet dressings of 10 grain strength solution, renewed two or three times a day.

Mode of Preparation.

1. The solution must be made by adding 5 to 7 grains to 1 pint sterile water at 112° F., left to stand for two hours, and should not be filtered.
2. Or a 10-grain to 1 pint solution can be used with dressings or Carrel-Dakin tubes, etc.
3. In very septic cases, swarming with anaerobes, etc., a 20-grain to 60-grain solution may be used.
4. It should be made fresh every seven days, and the bottle shaken before using.

Pure hydrogen peroxide is very unstable and momentary in its oxidizing power, while acetozone in solution is a fairly stable antiseptic, and its ozone-producing power is prolonged. Acetozone has a remarkably pleasant, pungent ozonic odour, the solution is colourless, and does not stain linen. Used in a 20-grain solution it is an efficient sterilizer of the skin.

Professor Hewlett has made bacteriological experiments with this drug, and reports as follows:

REPORT ON TESTS OF THE GERMICIDAL POWER OF ACETOZONE.

BY PROFESSOR HEWLETT.

At the request of Lieut.-Colonel Gore-Gillon, R.A.M.C., we have carried out a number of tests on the germicidal power of acetozone (benzoyl-acetyl-peroxide). The tests have been done with the *Staphylococcus pyogenes aureus*

and *Bacillus mycoides* (the latter as a type of a sporing organism). The method employed has been as follows:

A saline emulsion of an agar culture is made containing an approximately known number of organisms. Measured volumes of the emulsion and of acetozone solution (unfiltered) of known strength are mixed, kept at 37° C., and subcultured at certain time intervals. In some instances serum or broth has also been added to the mixtures. The following table shows some of the results obtained:

Staphylococcus Pyogenes Aureus.

SALINE MIXTURES.

Approximate number of organisms in mixtures = $2,000 \times 10^6$ per c.cm.

Strength of Acetozone in Mixtures.	Time of Exposure at 37° C.	Result.
1 in 1,750	1 hour 45 minutes	+
1 in 875	" "	+
1 in 513	30 minutes	-
1 in 437	24 hours	-
1 in 510	24 hours	-
1 in 872	24 hours	-
1 in 1,744	24 hours	-
1 in 4,370	24 hours	+
1 in 4,370	24 hours	-

This table shows that in saline mixtures acetozone 1 in 600 or thereabouts kills with an exposure of thirty minutes; and 1 in 4,000 or thereabouts kills with an exposure of twenty-four hours.

With an addition of one-third sterile human serum to the mixtures, acetozone 1 in 437 killed, and 1 in 654 did not kill, the staphylococcus with an exposure of twenty-four hours.

With an addition of one-third sterile nutrient broth to the mixtures, acetone 1 in 1,744 killed, and 1 in 4,370 did not kill, the staphylococcus with an exposure of twenty-four hours.

With sporing *B. mycoides* in saline mixture, acetozone 1 in 437 killed with an exposure of one hour. With an exposure of twenty-four hours, acetozone 1 in 1,744 killed, 1 in 4,370 did not kill.

With the addition of one-third serum to the mixtures, acetozone 1 in 437 with an exposure of twenty-four hours did not quite kill (there was no growth in the subcultures after twenty-four hours, but some growth after forty-eight hours' incubation). This was the highest strength tested.

With the addition of one-third sterile nutrient broth to the mixtures, acetone 1 in 1,744 killed, 1 in 4,370 did not kill, with an exposure of twenty-four hours.

We were able to make only one experiment with pus (staphylococci). Equal parts of pus and acetozone solution (giving 1 in 437 in the mixture) did not kill with exposures of 20 minutes, 40 minutes, 60 minutes, 1½ hours, and 18½ hours.

Finally a meat-broth anaerobic culture made from a septic wound was tested; it contained large numbers of mixed anaerobic sporing bacilli. Acetozone 1 in 290 with an exposure of twenty-four hours killed.

The results show that acetozone is a potent disinfectant. In saline mixtures it kills the staphylococcus in strengths of 1 in 600 in thirty minutes and 1 in 4,000 in twenty-four hours. The addition of serum and of broth reduce its germicidal power, but it is still effective in strengths of 1 in 437 and 1 in 1,744 respectively with an exposure of twenty-four hours.

With sporing *mycoides* in saline mixture it kills in strengths of 1 in 437 in one hour and 1 in 1,744 in twenty-four hours. With an addition of one-third serum 1 in 400 kills in twenty-four hours. With a mixed culture of sporing anaerobic bacilli grown from a septic wound, 1 in 290 killed in twenty-four hours. (1 in 290 = 30 grains to the pint; 1 in 437 = 20 grains to the pint approximately.)

We are much indebted to Miss Lettice Digby, assistant in the laboratory, Military Hospital, Richmond, for the care and labour she has devoted to the conduct of the experiments.

At a meeting of the medical profession held in Osler Hall, Baltimore, on May 23rd, £28,560 was subscribed for Liberty Loan bonds.

The number of past and present students of St. Thomas's Hospital serving in connexion with the war up to August 8th was 972, of whom 39 have been killed in action or died on service, 60 have received British honours, 10 have received foreign honours, and 3 the Order of the Hospital of St. John of Jerusalem, while 101 have been mentioned 146 times in dispatches and for valuable services.

THE BACTERIOLOGICAL EXAMINATION OF THE BLOOD IN CASES OF IRRITABLE HEART.

BY

GRACE BRISCOE, M.B., B.S.,

PATHOLOGIST UNDER THE MEDICAL RESEARCH COMMITTEE AT THE HAMPSTEAD MILITARY HOSPITAL,

AND

CAPTAIN LYN DIMOND, R.A.M.C.,

BACTERIOLOGIST TO THE HAMPSTEAD MILITARY HOSPITAL.

(Report to the Medical Research Committee.)

In the BRITISH MEDICAL JOURNAL of November 13th, 1915,¹ a letter was published which intimated that organisms had been found in the blood of patients complaining of the symptoms associated with the condition known as "irritable heart," namely, breathlessness on slight exertion, palpitation on excitement or moderate exercise, giddiness, and sometimes fainting, precordial pain and a general lassitude. Further investigation showed that the first conclusions were not warranted. The following note gives the results of the blood examinations in two series of patients. The first series was examined at University College Hospital, the second at the Hampstead Military Hospital, Mount Vernon.

First Series.

In all, 92 cultures from 27 patients were examined. The first 32 cultures gave only one positive result, a Gram-positive micrococcus in pure culture. The organism grew in minute colourless colonies, and had to be frequently subcultured, as it died out in three or four days. It was difficult to class it either as a streptococcus or as a staphylococcus. In a hanging drop short chains of three and four could be seen, but diplococci were most common. In a film short chains of three and four could be seen, but the arrangement on the whole was staphyloid. The colonies remained minute after several subcultures. The organism, incubated at 37° C., produced acid when grown in saccharose, lactose, raffinose, inulin, salicin, mannite, and litmus milk. There was no liquefaction of gelatin at 20° C. The remaining 60 cultures of this series gave 8 positive results at a temperature of 37° C., and 14 positive results in duplicates incubated at a temperature of 20° C. The majority of the cultures produced a micrococcus similar in type to that described above, but some showed a bacillus.

Such a high percentage of positive results raised the question of contamination, and the suspicion was increased by the larger number of growths found in the duplicates incubated at 20° C. A series of control blood cultures in normal people was therefore undertaken. Twenty-four cultivations were made; cocci or bacilli were found in four instances. Tentative cultures made from the skin and the syringe, after sterilization, showed that the method used to sterilize the syringe was faulty. The syringes had been sterilized by drawing up into the barrel, three to six times, oil heated to 140° C., according to the method recommended by Sir A. Wright.²

Subsequent experiments³ showed that syringes may not be rendered sterile even by six syringefuls of oil heated to 140° C. A satisfactory method of sterilizing syringes was found to be as follows:

An all-glass syringe is fitted together with the needle attached. Alcohol is drawn through to ensure the absence of moisture. The piston is withdrawn about a quarter of an inch to prevent it adhering to the neck of the barrel after heating. The syringe is placed in a large test tube with a wool pad at the bottom, and the tube is plugged with wool. The whole is placed in the hot-air sterilizer, and the temperature raised gradually to 160° C. and kept at this height for fifteen minutes. The air is allowed to cool gradually, and the syringe is ready for use as soon as it is cool. It need not be handled or exposed to the air until the moment of employment. This method of sterilization was controlled by contaminating the syringes with known organisms. It was found that all organisms tested, including the spores of *B. subtilis*, were killed by this treatment. In the second series of observations this method of sterilizing the syringes was used.

Second Series.

The patients in this series were of the same type, and presented the same clinical syndrome as those in the first series. The skin was sterilized by lysol or sublimate, 1 in 1,000. Alcohol and ether were subsequently employed. The blood was taken from the median basilic vein. Various methods of cultivation were used:

(a) 4 c.cm. of blood were taken and distributed between four tubes, each containing 10 c.cm. of broth. (b) 6 c.cm. of blood were distributed between twelve tubes, each containing 10 c.cm.

of broth. (c) 10 to 15 c.cm. of blood were poured into flasks containing 100 c.cm. of bouillon with 1 per cent. saponin. This method had to be given up owing to the difficulty of excluding air organisms. (d) Blood was poured directly on to the surface of agar plates incubated at 37° C., and also at room temperature. (e) 2 c.cm. of blood were put into a sterile test tube, incubated for twenty minutes at 37° C., and then at room temperature for one hour. The serum was pipetted off, and 10 c.cm. of broth were added to the tube containing the clot. The tube was replaced in the incubator at 37° C. Other media employed were: 1 per cent. saponin broth, 1 per cent. sodium taurocholate broth, 1 per cent. sodium glycocholate broth, 1 per cent. sodium citrate, 0.9 per cent. saline, and media containing adsorbents—aluminium hydroxide, animal charcoal, iron hydroxide. Anaerobic methods were also employed. The cultures were kept for ten days or a fortnight and frequently subcultured.

In all, 96 observations were made on 43 cases. In no instance was any organism grown, except in the few cases which became contaminated by organisms from the air when the flask method was used.

Since the patients were of the same clinical type we may collate the findings in the two series. In the second series, when the methods of sterilization were controlled, the results were consistently negative; it may therefore be assumed that the positive results obtained in the first series were due to contamination. Using the methods of cultivation in general vogue we have failed to demonstrate the presence of bacteraemia in cases of "irritable heart," and must therefore conclude that bacteraemia does not play a demonstrable part in the pathology of this disease.

We wish to express our thanks to Captain H. S. Blackmore, R.A.M.C., for the help he gave in carrying out the first part of the investigations at University College Hospital.

TRAUMATIC RUPTURE OF THE SPLEEN.

BY

J. LIONEL STRETTON,

SENIOR SURGEON TO THE KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.

TRAUMATIC rupture of the spleen is rare in this country. The two following cases, which occurred within seven months, are worthy of record:

CASE I.

W. T., male, aged 24, had been acting as a dispatch rider in Egypt, where he had attacks of malarial fever.

On December 18th, 1915, at 1.30 p.m., he was riding his motor bicycle, when he collided with another. The impact was sufficient to throw him forward thirty yards. He was stunned, and, when picked up, was taken home and attended by Dr. Griffiths at 2 p.m. I saw him at 9 p.m. He was blanched; the pulse was 128; the abdomen was distended and immobile and dull in the flanks.

At 9.30 p.m., under a general anaesthetic, an incision was made through the left rectus. Five pints of bright blood and some clots were removed from the peritoneal cavity. The spleen was enlarged to three or four times its natural size and an irregular laceration could be felt on its upper surface. At this juncture the patient became so collapsed that it was impossible to entertain the removal of the spleen. Gauze was packed into the laceration, the lower portion of the wound was closed, and the patient returned to bed.

He rallied during the night. There was no further haemorrhage. He was given calcium chloride gr. xv every four hours. He remained much in the same condition until December 23rd, when he gradually sank and died, five days after the accident.

CASE II.

J. M., male, aged 14, working on a farm, on July 15th, 1916, at 9.30 p.m., was running down a bank, when he caught his foot in some fern roots and fell on an ant-hill. He states that he hurt himself so much that he lay there for half an hour before he was able to get up and walk home, a distance of only fifty yards. The pain was in his left testicle and there was a swelling on the left side of the scrotum. He vomited three times after he reached home. His mother put some fomentations on him. The next morning he was seen by Dr. Deacon, who ordered him into the Kidderminster Infirmary.

He arrived at 2 p.m.; he had been driven fifteen miles in a two-wheel trap and was sitting up by the driver and appeared to be well. He got down and walked to the ward. He was said to be suffering from a hernia. I saw him at 3 p.m. He did not appear to be ill; the temperature was 97° and the pulse 106. There was no swelling in the scrotum, but when he coughed there was a protrusion from the abdomen into the scrotum, which was easily returned. It felt like a portion of omentum

with some fluid. He denied any sign of a hernia previously. The abdomen was not distended, the movements were free, and there was no rigidity. There was some dullness in both flanks.

At 3.30 p.m., under a general anaesthetic, an incision was made for radical cure of left inguinal hernia. The sac was isolated; before applying the ligature it was opened, when a quantity of blood poured out; the operation for radical cure was completed. The abdomen was opened by an incision through the left rectus. About two pints of blood and clots were removed from the peritoneal cavity. The spleen was felt to be lacerated. It was lifted out and the pedicle tied. The cavity was sponged out and the wound closed in layers. The spleen weighed seven and a half ounces, and was lacerated in four places.

The patient bore the operation well. He gradually improved and the wounds healed. He had an attack of acute parotitis at the end of August, which delayed his recovery, but he was discharged on October 5th. He looked well, and did not appear to suffer any ill effect from the loss of the spleen. He is now at work again and enjoying his usual health.

The contrast between these cases is interesting. The first patient had an enlarged spleen, which predisposes to rupture. The violent nature of the accident was sufficient to make us suspect a serious injury. Although the operation was performed eight hours afterwards, the loss of blood was so great that the patient was unable to recover from it. This result was favoured by the concussion, which prevented a sufficiently early recognition of the abdominal condition. Although it was not possible to remove the spleen this did not affect the result, as there was no further haemorrhage. In the second case the spleen was of normal size, and there was no predisposing cause of rupture. The accident was not severe, and did not make us suspect a serious injury. Although the operation was not performed until eighteen hours afterwards, the loss of blood, though serious, was not sufficient to prevent recovery. If the hernial sac had not been opened the condition might not have been discovered, as it was obscured by the sudden appearance of a hernia and by the moderate nature of the constitutional symptoms. It is difficult to believe that a boy could sit up in a shaking trap and drive fifteen miles over a very hilly road with such severe injuries.

A CASE OF "SPONTANEOUS" RUPTURE OF THE SPLEEN: SPLENECTOMY: RECOVERY.

BY

CAPTAIN W. RANKIN, R.A.M.C. (T.C.),
MEDICAL OFFICER IN CHARGE SURGICAL DIVISION, NO.—GENERAL HOSPITAL, R.E.F.

THE case is published for two reasons, first, on account of the rarity of rupture of the spleen as an abdominal catastrophe in this part of the world, and secondly, so that medical officers may be reminded of the necessity of examining the spleen in cases who have served for a period abroad.

I am indebted to Lieut.-Colonel Hayes, R.A.M.C., for his permission to publish the notes on this case.

Pte. P., aged 26 (service seven and a half years), was admitted to No.—General Hospital on March 29th, 1917.

He complained of acute abdominal pain and was cold, collapsed, somewhat cyanosed, and without any perceptible radial pulse. The abdomen was not rigid. There was dullness in the left flank. The liver dullness was present and normal. The patient had an "appendix" scar in the right iliac fossa. A lung lesion and locomotor ataxy having been excluded the case seemed clearly an acute abdomen, though its nature was doubtful. Marked cyanosis of the finger-nails was noted, and Colonel Hayes suggested the spleen as the focus of mischief, when the patient remarked "that some had said malaria was his trouble."

Operation.

Immediate middle-line laparotomy was performed. Captain Frew, R.A.M.C., gave the anaesthetic, and Captain F. T. Hill, M.C., R.A.M.C., assisted. On opening the peritoneum free blood was at once found. The wound was enlarged, and a very big spleen was quickly delivered through it. The capsule of the spleen was torn, and the torn surface was covered with firm clot. The pedicle was clamped and the spleen removed; the vessels were secured with a Staffordshire knot. Nearly two pints of blood were then wiped out of the pelvis and the kidney pouches; when the peritoneum was clean, the abdomen was closed with through-and-through silk-worm-gut stitches. Salines, morphine, and stimulants aided the rallying of the patient. His wound healed well, and surgically he made a good recovery.

The blood examination showed the parasite of malaria present in very great numbers. No crescents were found, and,

whilst the case looked a malignant one, the opinion expressed was that he had a double infection of tertian ague. This condition seemed to settle after a course of quinine, followed by one of liq. arsenicalis.

Previous History.

The patient had served in India for three years. There he had "an odd day or two" with attacks of malaria, but was never in hospital, and no blood examination was made. From November, 1915, to December, 1916, he was at Salonica. In August, 1916, he had an attack of malaria for which he was detained five days in hospital and then attended for three weeks, taking quinine. He was invalided home after an operation for appendicitis. From the beginning of 1917 he began to notice that heavy work and "jumping about" gave him a feeling of discomfort in his stomach, and after such exercise he vomited on several occasions. He was not short of breath, and thought his discomfort was due to his appendix operation. He arrived in France the day before his admission to hospital. He had been uncomfortable for five days before that, but had suffered no special trauma on land or sea during that time. He marched to his dépôt, took ill with bad abdominal pains during the night, and, when seen by his medical officer, was immediately sent to hospital. The spleen after removal was about eight times the size of the normal organ; it must have been much larger before it ruptured. The patient was transferred to England very well on May 14th, 1917.

THE EARLY TREATMENT OF COMPOUND FRACTURE OF THE FEMUR CAUSED BY GUNSHOT WOUND.*

By CAPTAIN R. C. DUN, R.A.M.C.(T.F.).

GUNSHOT WOUND, causing compound fracture of the femur, must certainly be looked upon as one of the gravest of war injuries. A more widespread appreciation of sound principles of treatment, and a thorough application of those principles, will, I feel confident, lead to improved functional results.

In no class of case is it more important that the treatment be early and adequate. I emphasize both adjectives.

This note is chiefly based on the practical experience which I have gained in working at casualty clearing stations, and, in the main, deals with the treatment carried out in them. But it has become obvious to me that it is the regimental medical officers and field ambulances in front of the casualty clearing stations who have in their hands the power of giving these cases the best possible start in their race for life. To obtain the best results a definite line of treatment must be adopted as early as possible—that is, by regimental medical officers and field ambulances, and carried on at casualty clearing stations.

What are the factors which we have to fight in these cases of compound fracture of the femur, and how can they best be dealt with before and after reaching a casualty clearing station? Broadly speaking, they are: (1) Shock, (2) haemorrhage, and (3) sepsis.

Shock.

I think we may fairly divide the shock from which these cases suffer into two classes—(a) and (b). The former is due to the gravity of the injury and the pain necessarily caused, especially in the earlier stages of transport, before complete immobilization of the fractured limb is possible; morphine and the best available fixation of the limb is the obvious treatment. Hot drinks, hot-water bottles, and saline injections should be made use of as early as possible. I submit that, up to the time when the patient can be put on a stretcher, a method probably as good as any is to fix the thigh with short local splints and to tie the thighs and legs together.

It is to the second class of shock that I particularly want to draw attention. This is the shock which results from the often unavoidable incomplete fixation of the fractured limb, and frequent handling of the patient in his journey from the field to the ambulance. In my opinion the best and simplest method of completely immobilizing a fractured femur is a properly applied Thomas splint, and this should be put on as early as possible; it would be ideal if it could be done at regimental aid posts or advanced dressing stations. Another ideal would be attained if cases of fractured femur could be transported from advanced dressing stations to casualty clearing stations

without removal from the ambulance, so reducing the movement of the patients to a minimum.

I have no hesitation in saying that cases of compound fracture of the femur which have had a Thomas splint applied early, and which are rapidly sent on to the casualty clearing station, arrive there in much better condition than similar cases imperfectly immobilized and subjected to movements during transit.

Haemorrhage.

As regards the treatment of haemorrhage before the case reaches the casualty clearing station, there is strong reason for avoiding the prolonged use of the tourniquet, on account of the increased risk of gas gangrene so entailed by producing anaemia of already devitalized tissues. Large vessels may have to be ligatured, or the patient may be sent down with artery forceps on. The most frequent form of haemorrhage, and one which should always be vigorously dealt with, is slow oozing from the wound. No case should ever be sent down until this has been checked. To do this, wounds often have to be opened up and ligatures or forceps applied to the bleeding points. Failing this, direct pressure with a firm packing of gauze into the opened up wound is often sufficient to check general oozing. A cork of gauze is worse than useless.

Sepsis.

To combat sepsis in the early stages, all that can be done is rapid disinfection of the skin for a considerable area around the wound or wounds. For this purpose a 5 per cent. solution of picric acid in methylated spirit is less irritating and more searching than iodine. Except for the necessary treatment of haemorrhage or the removal of visible foreign bodies, the wound should not be interfered with. The insertion of drainage tubes is unnecessary. Dressings should only be changed if soaked with blood.

Treatment at Casualty Clearing Stations.

Arrived at the casualty clearing station, all cases of compound fracture of the femur should be disturbed as little as possible, and sent without delay to the pre-operation ward. No case of this type should be evacuated to the base without first passing through the theatre. Small superficial wounds are deceptive, and invariably cloak much more extensive damage of the deeper tissues. Cases in which haemorrhage is taking place will naturally be given precedence in going to the theatre. Wherever possible inadequately splinted cases should also have next precedence; when this is not practicable the fixation should be improved. The greatest care must be exercised to prevent increase of shock by unnecessary movements; thus no attempt should be made to remove the clothing from the injured limb until the patient is anaesthetized, and he should not be lifted off the stretcher on which he arrives until anaesthesia is complete. The usual methods of treating shock—warmth, morphine, camphor, and salines—will be employed in cases which have to wait their turn for operation.

When the case reaches the operating theatre care must again be taken that no increase of shock occurs from unnecessary or rough handling of the patient. Probably the soundest plan in all cases is to lift the stretcher on to the operating table, and anaesthetize the patient before he is removed from the stretcher. The only circumstance which may justify an exception to this rule is an efficiently applied Thomas splint.

With a view to shortening the time occupied by the operation and to ensure smooth working, all members of the operating team should have been made thoroughly conversant with the details of the technique. Where multiple wounds are present, a second operator should get to work on them at the same time that the femur is being treated. The only reference I will make to the question of the choice of an anaesthetic will be to point out the advantage of spinal anaesthesia in some cases of fractured femur—for example, when associated with a penetrating chest wound.

Shock must be vigorously combated on the operating table. Warm blankets, hot-water bottles, salines, subcutaneously or intravenously, should be used. In all grave cases, the latter is the method of choice, and it should be employed at the start of the operation. As soon as the

* Paper read at a meeting of medical officers of an army in the field.

patient is anaesthetized he is lifted off the stretcher, splints are removed, and clothing cut away. The limb is then raised from the table by means of a rope and pulley apparatus, attached to a clove hitch round the ankle (see Fig. 1). By this means the limb can be elevated and

FIG. 1.—Fracture of femur. Diagram of rope and pulley apparatus for raising leg from operating table.

extended at the same time. This simple device frees the orderly from the somewhat arduous task of holding up the limb during the whole period of the operation.

The preparation of the skin must be thorough. A wide area round the wound or wounds and the whole circumference of the limb should be treated, as unexpectedly extensive incisions are often necessary.

An important detail is the secure fixing of sterilized towels round the upper part of the limb. Clips should be used which fix the towels to the skin, as they are apt to become displaced during the changes in position of the limb which have to be made in the course of the operation. The leg and foot should be wrapped in a sterilized towel, under cover of which is the suspension sling, or the hands of the orderly supporting or adjusting the leg.

The first step in the actual operation should be excision of the superficial wound, followed by a determination of the main pockets with the finger. The wound should then be opened up in the direction of these pockets, unless this entails the division of important structures. The full extent of the injury to muscles and bone must be seen. The eye must be our guide as well as the finger. It is only when a thorough survey of the injury has been so obtained that the operator is in a position to decide the subsequent course he should adopt in each particular case. The size of superficial wound is no indication of the deeper damage. Most extensive laceration of muscles and severe comminution of bone very frequently underlie apparently trifling skin wounds.

The Question of Amputation.

The full extent of the wound having been appreciated, the question of amputation will arise in a proportion of cases. In some hopelessly mangled limbs the decision is easy. There are again many borderland cases where there is great difficulty in deciding what is the proper course to steer. I think it is a good plan to hold consultation in such cases. Amputation should be performed:

1. Where the main vessels, both artery and vein, are divided, and collateral circulation has not been established; unless, as happens in rare early cases, some form of blood vessel anastomosis can be performed—for example, by intubation with paraffin covered glass tubes, until danger of gas gangrene has passed.

2. Where gas gangrene is definitely established in more than one group of muscles, or where, for anatomical reasons, complete excision of any infected part cannot be carried out.

3. Where either the main artery or vein requires ligature, and there is evidence of even a localized patch of gas gangrene beyond the point of injury to the vessel.

4. Where virulent sepsis is already established in extensive wounds, the patient being in low condition.

In cases where the general condition of the patient is bad, especially as a result of haemorrhage, one's leaning should be towards amputation.

Involvement of the knee or hip joint does not by any means necessarily call for amputation. The same may be said of extensive laceration of muscles and severe comminution of bone—if the circulation is good, and there is no evidence of gas gangrene in the wound.

When amputation is decided on, the circular or modified circular method—as low down the limb as possible—is the one which should be employed. When sawing the bone, a strong flat metal plate, with a slot in it to admit the femur, is useful in keeping muscles out of the way and in saving time. In order to prevent superficial necrosis of the sawn bone, a layer of deep muscle fibres may be stitched over it. The dressing used is either a "salt pack" or Carrel's method. Such amputation stumps are ideal wounds for the application of a salt pack. A practical point is that room should be left between the skin edges for drainage when the strips of adhesive plaster are being applied.

Conservative Treatment.

I should like again to emphasize that, in addition to the careful removal of foreign bodies, the superficial wound must be completely excised, and all badly lacerated fascia and muscle cut away. With regard to the muscles, contraction alone is not a sufficient guarantee of the necessary degree of vitality—definitely bleeding muscular tissue must be reached before one holds one's hand. Great care must be taken that the vascular supply of muscles previously treated be not cut through during the later stages of the operation. Once embarked on such an operation, there must be no half measures. Most extensive dissections may have to be carried out. There must be no hesitation in cutting wide. The principles which guide us in the operative treatment of malignant disease must be applied. One small piece of devitalized muscle left in the wound may be sufficient to render the whole procedure useless. Bone fragments, unless completely separated, should not be removed.

If a joint has been directly opened by a missile, the damaged portions of the capsule and synovial membrane must be cut away. The joint is then washed out and the opening into it closed with sutures. A drain should always be employed down to, but not into, the capsule.

Perfect haemostasis is essential. The operative technique is the same whatever form of after-treatment is followed.

After-Treatment.

Practically speaking, there are but two methods of after-treatment: the pack (at present the "salt pack"), and Carrel's method. The difficulty in applying a pack to many of the wounds associated with fracture of the femur is considerable. One should always ask oneself: Can any given wound be completely and accurately packed, and, if this can be done, will the necessary pressure so applied increase the risk of gas gangrene? In any case in which a main vessel has been injured, a salt pack should not be employed, as the requisite pressure may interfere with the establishment of the collateral circulation. If any doubt exists it is wise to use Carrel's method. Where a pack is put in, a drainage tube should be inserted down to, but not between, the bone fragments—the tube coming out through the centre of the pack.

The operation completed, all that remains to be done is to immobilize the limb. Incomplete fixation may lead to failure, in spite of the most careful operative treatment.

Fixation by Thomas's Splint.

A "Thomas splint outfit," properly used, is the simplest and most efficient method of obtaining complete fixation.

The detail of the application is, shortly, as follows (see Fig. 2):

1. The suspensory sling is removed from the ankle and the limb is supported by an orderly.

2. Application of Extension Bandage.—It is not necessary to shave the limb. Paint the entire circumference from the malleoli upwards, sufficiently high to allow the

extension to get a good pull on the lower fragment, with a glue solution, of which the formula is—

Glue	1				āā	50 per cent.
Water			
Thymol		$\frac{1}{2}$ per cent.
Glycerin						
Calc. chloride		āā	2 per cent.

A shaving or small painter's brush is used for applying the glue. During an action a pot of this glue should always be kept ready melted. The glue will become too thick after a time, and a little water should then be added.

Next apply, on either side of the limb, a length of bleached calico bandage, and run a roller bandage round the limb.

3. Application of Splint.

—The ring of the splint is passed over the foot and pushed upwards, until the posterior part of the ring presses firmly against the ischial tuberosity.

4. *Tightening of Extension Bandage* (Figs. 3 and 4).—The surgeon takes an extension bandage in each hand and passes one of them over, the other under, the lateral bars of the Thomas splint. First one bandage and then the other is thereafter passed round the notch in the cross-bar, a complete turn being taken in each case. The turns are taken in opposite directions, and the last overlaps the first. The ends are made secure by tying a half-bow.

5. *Application of Slings.* — In

cases where the wounds are in such a position that it will be necessary to remove the ham splint for dressing purposes, slings formed by bandages or, better still, perforated zinc strips should be applied at this stage.

6. Application
of "Ham"

Splint.—This should be padded to suit each case. Moss pads serve the purpose well. Over these a sheet of jaconet is placed to prevent soiling. The ham splint is now slung to the side bars of the splint by three strips of adhesive plaster—the adhesive side being next the ham splint. This effectively prevents lateral movement of the ham splint.

7. *Application of Anterior Thigh Splint.*—The splint consists of a piece of Gooch's splinting applied to the thigh, canvas side towards the limb. It should extend from near the ring of the Thomas splint to just above the patella. A number of suitable lengths of Gooch's material should be cut beforehand. The whole roll may be sawn through; an orderly can cut off any breadth

required. The thigh splint is fixed by the bandage, which is now applied to the limb from the ankle upwards. This bandage encircles all the splints.

8. *Application of Foot-piece.*—The foot must be supported at a right angle by means of the metal foot-rest, which is supplied with the outfit. A bandage sling passed round the ball of the toes, fixed there by glue on the sole of the foot, and pinned on either side about the knee level to the bandage which surrounds the limb, is perhaps more comfortable to the patient. An oblong piece of splint, rather longer than the breadth of the foot, padded thinly and covered with jaconet, will prevent the bandage press-

ing on the sides of the foot. Glue will prevent slipping of both bandage and splint.

9. *The Suspension Stretcher Bar should always be Used.*—To this the Thomas splint is slung by two pieces of bandage, one attached to

FIG. 2.—Fracture of femur. Diagram of application of "Thomas splint outfit" for transport of fracture of femur.

either bar of the splint. If no suspension bar is available, the leg must be slung by some other means.

Similarly, if the patient cannot be evacuated, the injured leg must be slung in the wards. A simple method is the use of two bandages, each passed over a beam of the hut. The two ends of one bandage are then tied to the bars of the splint close to the ring. The ends of the second bandage are secured to the bars at the level of the foot.

Evacuation.

Many cases of compound fracture of the femur may safely be evacuated as soon as they have recovered from the anaesthetic. Before evacuation the extension should always be inspected—the bandages may require tightening or loosening. A pad of wool may be required between the ring and antero-external part of the thigh, so as to prevent the ring from nipping the scrotum or slipping off the tuber ischii.

In cases which have to be kept at a casualty clearing station for more than twenty-four hours, the superficial dressing

should be changed before evacuation, on account of oozing. Here also care must be taken of the skin pressed on by the posterior part of the ring—it should be pulled up to change the point of contact, and carefully dusted. Alteration of the degree of elevation of the splint, or propping up the patient, frequently adds to his comfort.

The abduction frame should be used for fractures of the femur so high up that the upper fragment cannot be

FIGS. 3 and 4.—Fracture of femur. Method of tying the extension bandages so as to prevent slackening of the adjustment and loss of time during adjustment. Pull and hold a taut (Fig. 3). Pull and hold B equally taut, thus fixing a at c. A may now be left loose. Tie loop knot with a on B and draw tight up to c (Fig. 4). In adjusting, hold B taut; undo loop knot; hold A taut and pull to its own side. Pull B taut, and proceed as above, merely substituting B for A.

controlled by the anterior thigh splint. The method of its application is indicated in the official memorandum on "Treatment of injuries in war."

MEDICAL, SURGICAL, OBSTETRICAL.

CONGENITAL DEFICIENCY OF PHALANGES.

THE accompanying radiograph (taken by E. Terry Coppin) and photograph are those of the left hand of a young woman whom I examined as an entrant to Woolwich Arsenal. She was a dressmaker by trade, anxious to do her share of work in munitions. She was rejected by a labour exchange on account of the deformity of her hand, but was brought to me by her sister, who had been passed as suitable. Although she had apparently only one phalanx to the first finger and to the thumb, she could grasp firmly and had considerable power in the first two fingers and thumb. There were no nails.

No family history and no antenatal history were ascertainable. The girl was passed as medically fit, and she is at present engaged in "ringing fuses" as expertly as any worker in her shop.

London, W.

ELIZABETH SLOAN-CHESSER, M.B.

DERMATITIS FROM EXPLOSIVES.

I WISH to express my own thanks and those of my brother-officers in this ambulance to the authors of the contributions on the above subject. They solve the mystery of a case we had to deal with a few nights ago. A young soldier was brought in with a deep erythematous rash over both buttocks. The portions of skin affected were very tense and painful, and, on the right, vesicles of varied minute sizes had developed. I asked if a German shell had recently burst near him. His history was that eight days previously a shell had burst some yards distant from him while he was sitting over a pole on an open latrine with his gluteal region exposed. Further than a shower of light earth he felt at the time no serious consequences of the explosion. Till the morning of his admission to our ambulance he felt all right. On that morning he felt intense pain in the right hip, and discovered the rash. It seemed to us at the time like a case of shingles, though its bilateral character was unusual. The long interval between the explosion and the appearance of the rash seemed to annul the likelihood of any connexion between the two. The case was sent to a casualty clearing station as one of dermatitis. It is obvious now that powder from the explosive had been conveyed with the shower of earth which he felt on the unprotected parts.

RESUSCITATION OF THE NEW-BORN INFANT BY HEART MASSAGE.

I HAVE had some experience in midwifery, having attended over 2,200 cases in thirty-five years, but I have not before this come across an instance in which I have been able to revive a child when the heart impulse had ceased.

The labour was one in which the head was delayed by a very deep perineum in a primipara. Chloroform was used and delivery completed by forceps, the perineum being torn to the anal margin. No time was lost in extracting the child. The child was more white than blue. Artificial respiration was of no use even after blood had been allowed to flow from the cord.

I had read lately of a successful case of heart massage performed in an operating theatre by incising the epigastrium and massaging through the diaphragm, and as there was not any heart beat at all, I tried massage.

I pressed my right fingers deeply into the left epigastric region, and pushed them right under the ribs, invaginating the belly wall, the left fingers pressed in the chest about the left nipple, and I was able to grasp the heart. I tried to make my two sets of fingers meet by repeated quick thrusts, and after five or six the heart started beating. In about one or two minutes it was fairly established, and then ordinary artificial respiration caused the child to breathe in about five minutes; keeping it up I got a good cry before ten minutes had gone by. The child

never had a throw back afterwards, but bruising showed itself where my fingers had pressed in the skin.

As a rule, one finds a heart beat in these cases, and continues artificial respiration as long as a heart flutter can be detected. Hitherto, if that heart flutter has ceased, one has considered that no more can be done. Now I am convinced that heart massage as described will most probably set the heart going again,

and then artificial respiration will complete the process.

Whether the cardiac stoppage was due to the chloroform I cannot say. Certainly the mother did not have an overdose, as she was sufficiently round to implore me to save her child if I could.

Rebielus.

CAUSATION.

DR. MERCIER'S book, *Causation, with a Chapter on Belief*,¹ is polemical. Polemics are usual in essays on causation, and normal in chapters on belief. But, in addition, it has the rare merits of wit and lucidity. One gets a first impression of a jolly thing, almost a skit, dashed off in gay high spirits. All sorts of reverend people—Hume, and Mill, and lesser lights—are scalped with zest and enjoyment. But the first impression is wrong. Here is no skit, but an extraordinarily thoughtful and convincing, and withal original, piece of work. The proof lies in the fact that, though we smile as we pass easily from chapter to chapter, yet, afterwards, we find that we have looked, often more deeply, always more clearly, into matters that have been treated with dreadful obscurity for centuries.

It is impossible to review the essay adequately. It consists of a chain of reasoning of which an examination would require as much space as the work itself. It is possible to indicate only its point of view.

What is a cause? What is causation? Every one thinks he knows. In a sense, every one does know. According to Dr. Mercier, "the notion of causation is almost elementary. Cause and effect, like matter and force, are terms which every one understands more or less vaguely, more or less precisely, but that it is difficult to express more simply for want of simpler terms." Here, near the beginning of the essay, is adumbrated a particular point of view which is held consistently to the end—the view-point of science as distinguished from metaphysics.

In front of the reader is a printed page. He may consider it in two fundamentally different ways.

1. He may regard it as a real object in a real universe—

¹ On *Causation, with a Chapter on Belief*. By Charles A. Mercier, M.D., F.R.C.P., F.R.C.S. London: Longmans, Green, and Co. 1916. (Roy. 8vo, pp. 240. 4s. net.)

a universe which was not created by his mind, but is independent of and merely observed by it, which existed before his mind, and will have being after his mind has ceased to be. That is the view of common sense and of science. The ordinary man believes *unquestioningly* in the objective existence of his body, his wife, his child, his whole world. He believes, moreover, that they are such as his senses tell him they are, such as they seem to be. Read any book of science—astronomy, geography, chemistry, botany, anatomy, and the rest—and you will find that the view of the author is exactly similar. He has an *unquestioning* belief in a real universe in which his objects of study—stars, men, and the rest—are such as they seem to be.

2. Or the reader may delve deeper. He can see and feel the paper and hear it crackle. But every sensation through which he learns about the paper is a feeling *in him*. It is part of his mind, not part of the paper. Moreover, no feeling—for instance, the feeling which he calls a vision of the page—can be remotely like the reality. How can an immaterial feeling be like a material object with which it has no single property in common? At best the feeling can be only a sign, a symbol, of the material object—much as the written word "page" is a symbol (totally unlike) of the spoken word, and the spoken word a symbol of the vision. Moreover, is there any real object? How is one to know that the page is not a pure hallucination? We cannot get outside our feelings, which lie to us during our dreams, and may lie equally during our waking hours. How is it possible to know whether there is anything in the universe besides one's lonely, amazed mind? There you have the metaphysician. His distinguishing mark is a refusal to accept *unquestioningly* the assumptions from which science and common sense start. He tries to go deeper. That constitutes him a metaphysician. The reader is a metaphysician at this moment. Some metaphysicians, the idealists, conclude that there is only (or evidence only of) mind. Others, the materialists, suppose that there is also matter; clearly the latter are guessing. They cannot get outside their feelings.

If we adopt the scientific standpoint, a rich and illimitable field spreads before us. Objects are innumerable, and have properties and relations by means of which they can be classified and by means of which they can influence one another. For instance, a real moving stone strikes a real fragile pane of glass and breaks it. Here we understand cause and effect as well as we understand anything. We cannot put the matter in simpler terms, for already it is perfectly simple. It would be like trying to simplify the statement that $2 + 2 = 4$. On the other hand, if we adopt the metaphysical standpoint, we are in a cul-de-sac. Why should this feeling, this appearance of a moving stone, always seem to produce such an effect on that other phenomenon, the pane of glass? The thing is more incomprehensible than if, in a real painting, the appearance of a stone suddenly broke the appearance of a pane of glass. Cause and effect are incomprehensible to the metaphysician because the causing and affected appearances are themselves incomprehensible. He is on safe ground as long as he contemplates his feelings in silence, but directly he opens his mouth and tries to account for them he is in difficulties.

No one has known a consistent idealist (the common sort of metaphysician), for all known idealists have had an itch to explain in words (mere phenomena) to other people (mere visions) that they, with the rest of the universe, are mere appearances created by the idealist's mind. It is as if one asked one's conception of a friend to drink one's perception of a glass of wine. In real life only lunatics do that kind of thing. The most astounding kind of idealist is the very modern type who insists that science is concerned only with phenomena, denounces metaphysicians, and then, perhaps, discusses the age-long evolution of worlds and living beings (creations of his mind of yesterday). Such a one should be certified and sent to an asylum. Not only is he obviously insane, but he has stolen a sacred name and used it to deceive innocent men of science who know as little of metaphysics as metaphysicians of science. He has spoilt two good things.

Though metaphysicians cannot understand how anything can cause (that is, enforce) anything else, they note that certain phenomena seem always to follow or accompany certain others. Thus, if the phenomenon Tom

seems to smite the phenomenon Dick vigorously on his phenomenal nose, bleeding always seems to follow. It is this "always," this "invariable succession," that has, according to metaphysicians, originated the idea of enforcement. Why should the appearance of a blow cause the appearance of bleeding any more than the appearance of a flower garden? But, in this visionary world, Tom has phenomenal legs and arms, and a heart, and a liver, and a rage against Dick; therefore, since these things are always present, they are as much causes, "invariable antecedents," as the blow. Since only metaphysicians have written on this subject, the notion that every condition is also a cause is the accepted view among "intellectuals."

But, if you ask a man of science what causes the bleeding, he will tell you of the rupture of real blood vessels in Dick's real nose, or, as more remote causes, of the blow, Tom's animosity, or Dick's offence. The liver and similar things will not occur to him. Now Dr. Mercier, for the first time in history, puts this common-sense view into precise language and rescues it from the imputation of ignorance and thoughtlessness. According to him, "A cause is an action . . . connected with a sequent change . . . of the thing acted on." For him the idea of enforcement is clear. The rupture of the blood vessels, the blow, and Tom's rage are links in a chain of real causation. Whereas the liver, and the like, are merely *necessary conditions*—necessary because without them Tom would not be alive, and therefore could not punch Dick's nose.

We have dealt only with the view-point of this excellent book. It contains immensely more—all as clear cut and sparkling and attractive as a diamond. The author does not even declare that he maintains the scientific as distinguished from the metaphysical view of causation. But such is actually the case. And he is a pioneer. In future the metaphysician will not have it all his own way. The essay does not fall within the limits of what is commonly regarded as science; it is concerned rather with the foundations on which science is built. But, if the followers of science had a clearer insight into the nature of these foundations, it is certain that we should have less argument and more agreement, less guessing and more established truth, and above all, less of that horrible mixture of science and metaphysics which poses to-day as the purest science—such stuff as this, for instance, "The law of gravitation is not so much the discovery by Newton of a rule guiding the motions of the planets as his invention of a method of briefly describing the sequences of sense impressions which we term planetary motion."

NOTES ON BOOKS.

In The Passing of the Great Race? Mr. MADISON GRANT essays to trace European history, and illustrate its meaning, in broad terms of heredity. As Professor H. F. Osborn insists in the preface which he contributes, race has played a far larger part than either language or nationality in moulding the destinies of man. This aspect of history, in the light of the great biological movement beginning with Darwin, Galton, and Weismann, is somewhat novel, since historians have hitherto failed to realize the potent, subtle influence of heredity always at work beneath the more visible and transitory forces of environment. The modern science of anthropology seems to teach that somatic characteristics do not change through the ages. Mr. Madison Grant widens this doctrine to include a like immutability of the moral and intellectual traits which in the mass influence national development, and underlie all social and political action. Convinced of the danger of racial sentimentalism, he has written this book with the purpose of warning his fellow countrymen of the United States that if the lessons of evolution are not taken to heart, and applied to social legislation, the great race—mainly Nordic—to which is due all that is best in their national life, will be bred out of existence by other, and as he considers lower, types. While not prepared to go all the way with the author into the debatable region of practical eugenics, we can commend his treatise to serious students. The general reader, also, will find in it much to awaken interest.

²*The Passing of the Great Race; or the Racial Basis of European History.* By Madison Grant, Chairman of the New York Zoological Society. London: G. Bell and Sons, Ltd. 1917. (Med. 8vo, pp. 257; illustrated with maps and plans. 8s. 6d. net.)

THE ROYAL ARMY MEDICAL CORPS, AND ITS WORK.

THE general work of the medical service of the British army may be regarded as falling into three main sections:

1. The physical and environmental hygiene of the soldier's life.

2. The evacuation of sick and wounded from places at which their presence is an obstacle to the success of military operations, and detrimental to the men themselves; and

3. The provision and maintenance of institutions at which sick or wounded soldiers can remain during treatment.

In theory, and to some extent in practice, the area in which the work has to be done is divided into three zones. The first or forward area is known as the "collecting zone" (Fig. 1). In it the wounded are collected from the battle-

FIG. 1.—Collecting Zone. Diagram representing the distribution of the medical units. The plain circles are regimental aid posts. The circles with a dot in the centre are advanced dressing stations, and those with a cross are main dressing stations of field ambulances. The circles with a vertical line through them are rest camps and other annexes to main dressing stations. The upper oblongs are a couple of casualty clearing stations connected by road with the field ambulances and with the base by a railway line and canal traversing the evacuating zone. The oblong below (S.H.) is a stationary hospital in the evacuating zone. Opposite it is an advanced depot of medical stores (A.D.).

field, and the sick from the places at which they fall ill. Theoretically it is an area of the shape of a triangle, connected by its apex with the lines of communication, and having at its base the regiments in action; and nominally it contains only the regimental aid-posts, the field ambulances, and a "casualty clearing station," or railroad hospital, which stands at the apex, and serves to house the sick and wounded sent on from the field ambulances until they can be passed down through the evacuating zone to the distributing zone. In practice, however, it contains certain other units of a medical character.

The next or middle area is known as the "evacuating zone," because it is traversed by the roads, railway lines, or canals along which the sick and wounded are carried on their way to the distributing zone. It corresponds with the military area known as the lines of communication, and, theoretically, is long and narrow, containing, from a medical point of view, nothing but the various means of transport, and perhaps a medical store or two and a few "stationary" hospitals for the reception of patients who should not be taken any further towards the distributing zone.

The third or lowest area is called the "distributing zone," because in it are placed the various institutions among which the sick and wounded are to be distributed to receive their final treatment. It is an area of indefinite size, corresponding roughly to that in which munitions of war are gathered and reinforcements collected, and which, from a purely military point of view, is known as the base. In this war it lies partly in Great Britain, partly overseas, and consequently it is common to speak of it as if it contained institutions of two different orders—"home hospitals" and "overseas or base hospitals."

The collecting zones in France may be regarded as divided into sections, each with its own line of com-

munications and a railroad, for the front is actually held by different armies each of which has its own area of operations. Each such area is in medical charge of a senior medical officer known as Director of Medical Services (D.M.S.), who is responsible for the arrangements he makes only to the general of the army to which he belongs, and to the principal medical officer of the British forces—that is to say, the Director-General of Medical Services on the staff of the Commander-in-Chief.

In the collecting zone, even in parts of the area full of suggestions of the industries of peace, the dull booming of the guns is rarely inaudible, while a few miles further afield the road is encumbered from time to time by ammunition wagons, by ambulances, by fresh battalions going up to take their place in the line, or by battalions returning to their billets mudstained and worn. The hill-tops, too, disclose a view perhaps of swiftly moving aeroplanes, a line of observation balloons, and the rising smoke clouds formed by bursting shells.

This area has an atmosphere all its own—bracing, suggestive, thrilling, yet curiously solvent of illusions and of personal petty ambitions. That is its effect, at any rate, on many a newcomer. He sees himself suddenly from a new angle; he recognizes that he has arrived at a place where there is no room for the looker-on at life, at a place where men justify their existences by work and their deaths by altruistic aims, and where nothing counts but the war.

The various sections of this zone are each, as has been said, in charge of a director of medical services, who works through the deputy directors (D.D.M.S.) in charge of the corps into which every army is divided, and these again through the assistant directors (A.D.M.S.), who are responsible for the medical work of the divisions out of which army corps are constituted.

The number of men in a division is roughly 20,000, and to meet their needs each A.D.M.S. has at his disposition the personnel of three field ambulances, and twelve or more medical officers attached to single battalions or like divisional units.

BATTALION MEDICAL OFFICERS.

The battalion or regimental medical officers do their work in a more advanced position than any others, and in some respects are the most important components of the whole medical service.

Each is as it were the family medical attendant of the men of the unit, the medical officer of health of the locality in which it may for the moment find itself, and the private medical adviser of the commanding officer in respect of all questions in which medical considerations arise. He gets, or should get, to know the mental and physical peculiarities of every officer and man in his battalion—knowing, for instance, such things as who have dubious feet, who a nervous constitution, who are exceptionally hardy, who are careless in their living, who careful, who are disposed to go sick on the least excuse, who will never report themselves until positively obliged. He acquires this knowledge by going about among the men, by his formal medical inspections, and by noting who are the frequent attendants at his morning sick parades, and why they come. Bearing in mind that the sole reason why the men are in his charge at all is in order that they may fight, and fight effectively, he treats them much in the spirit of the medical attendant of a racing crew. Hence he is always endeavouring to tackle small evils early, and to winnow out the sick to whom he can afford all necessary treatment himself from those who must be sent elsewhere.

Everything that can in any way affect the health of his unit comes within his purview: food and its preparation, the sterilization of the water supplies, the provision of latrines and their proper maintenance, the destruction of rubbish, and the cleanliness of billets and dug-outs. He is always, too, on the alert for the first signs of an outbreak of any epidemic malady, wages war on parasites and flies, and endeavours to ensure that the men appreciate the importance of the various precautions they are told to observe, including those against trench feet. His authority he derives partly from his personal position, partly from his influence with the commanding officer of his battalion. If he secures the confidence of the latter,

and the real respect of the adjutant and the sergeant-major, his work is, from one point of view, easy.

His duties are continuous, whether his unit be resting in billets or be taking its turn in the fighting line.

TRENCH WORK.

If it be taking its turn in the fighting line he has also to attend to battle casualties and their evacuation, his precise duties in this connexion differing according as trench fighting is in progress or an "over-the-top" advance.

In the former case he does his work from a predetermined point chosen according to the lie of the ground and other circumstances, at or close sometimes to the head quarters of one of the companies of the battalion or sometimes to those of the battalion itself. The former are likely to be in a dug-out or trench some two or three hundred yards behind the fire trench, and the latter perhaps twice or three times that distance (Fig. 2). Here he establishes a first or regimental aid post, equipping it with the ordinary provisions of a surgery, coupled with bunks or other lying-down accommodation for, say,

half a dozen seriously wounded men (Figs. 3 and 4).

The aid post itself may be the cellar of a ruined cottage or house, a deserted German dug-out, or an ostensibly shell-proof annexe to a communication trench, but whatever its nature he endeavours to guard his patients against

of the post be at all considerable, he takes what steps he can to divide it up in such fashion that no single shell is likely to affect all parts of it.

To assist him he has a corporal and four men of his own corps, their specific duty being to look after the water supplies; he draws from the battalion a lance-corporal, a driver for the small cart in which he carries about his aid-post outfit, and from each half-company one man whose specific duty is sanitation. The unit also supplies him with men to act as stretcher-bearers in

FIG. 2.—Map, drawn from memory, showing the position of a certain regimental aid post lying between a main and an accessory communication trench. The shaded block is the post itself. It stands across the trench, the patients approaching along the curved trench and leaving by the straight descending trench, which leads to the advanced dressing station. The ascending arm leads to and from the firing line. The projection (K) on the right is the aid post kitchen. The projection (L) is the latrine. The small shaded projection (S) is a dug-out for four R.A.M.C. stretcher-bearers.

FIG. 4.—Elevation of the regimental aid post shown in Fig. 3. Tiers (S.P.) for stretchers for patients are seen on the left (one in position), and the M.O.'s bunk and stretcher bed on the right. In the middle is a trestle to support a stretcher while the case is being dressed, and near it a bench for bottles and dressings. Sufficient height for work (about 6 ft. 6 in.) is secured by slightly deepening the trench, inflow of water being prevented by a dam and sump pit. The floor is concrete; the roof, concrete, sand-bags and earth. Light is supplied by acetylene lamps.

the proportion of two to each half-company, or sixteen in all. His total command therefore consists of twenty-nine men, all of whom he trains in stretcher-bearer and first-aid work, but otherwise employs as he finds advisable. Subject to the specific duties mentioned he usually posts most of his men along the trenches held by his unit in order that they may be ready to attend the casualties when the cry "stretcher-bearers at the double" is passed from sentry to sentry.

The medical officer visits the fire trenches whenever occasion occurs, and often merely to encourage the men by the knowledge that should they be wounded skilled attention is at hand; his assistants are, however, competent in ordinary cases to apply the first-aid dressing which every soldier carries inside his tunic; if feasible, the wounded man is then removed to the regimental aid post. Consequently, it is here that the medical officer habitually remains.

If, however, the injury be a fracture of the lower

FIG. 3.—Ground plan of a regimental aid post shown in elevation in Fig. 4. On the left (O) is a bunk for two orderlies, each having his stretcher bed; next is the M.O.'s bunk, with a stretcher bed and table. In the centre compartment running from entrance to exit are trestles to support a stretcher while a case is being dressed, some tables and shelves for bottles and instruments, and two sitting benches. On the right is an empty space for storing the kits of patients, and beyond are slides, each to hold three stretcher patients, in tiers (S.P.). A curtain separates them from the centre compartment. Gas-proof curtains are rolled up above the doors ready to let down on a gas alarm, and on the floor near the exit is a cylinder of oxygen and a spraying machine and some bottles of anti-gas solution.

a gas attack, providing for all openings a blanket screen soaked in an anti-gas solution which can be lowered into place at a moment's notice. Also, if the accommodation

FIG. 5.—Diagram representing a section through a fire trench, measuring about 2 ft. at the bottom, about 4 ft. at the upper ground level, and about 6 ft. 6 in. from top to bottom. The shelf at the side, or fire-step, can be used as the foundation for a stretcher bed when the bottom of the trench is full of water.

limb or other serious condition, or the man cannot be brought back to the aid post forthwith, the medical officer goes up to see that the necessary steps are taken. These will always include the placing of the patient in some position in which he will be out of the way of the fighting men, while if the trench be waterlogged or the weather very rainy, and the patient helpless, it may be necessary to build him up a bed out of a stretcher on the fire step (Fig. 5), or elsewhere above the water line,

protecting him from cold and wet by blankets and a waterproof ground sheet.

The difficulty of getting a case out of the trenches varies with its nature, with the amount of the fighting that is in progress, and with the character of the trench leading from the place where the casualty has occurred to battalion headquarters. A plan of a common type of trench is shown in Fig. 6. Should the communication trench have

Fig. 6.—Outline of a common form of trench with traverses projecting towards the rear. The straight parts are the fire bays. On the left is the beginning of a communication trench. On the right is a latrine (L) leading out of a traverse. Many of the angles of such a trench are worn away.

been knocked about recently or be waterlogged, it may not be easy even for an active and unloaded man to get along it, and in the best of circumstances the transport of a wounded man along the trenches is a problem presenting much difficulty.

Certain types of new trench (Fig. 7) may be nowhere wider than 24 in., while the average width of a fully-developed trench is not more than 4 ft. at the level of the shoulders, and its course is invariably interrupted by angles round which an ordinary stretcher cannot be

Fig. 7.—Diagram of a type of trench presenting special difficulties in moving wounded men. It is a twin trench of which the front one is never more than about 2 ft. wide and 4 ft. 6 in. deep.

carried except by tilting. (Figs. 8 and 9.) Numerous special stretchers have been devised, and some of them meet their purpose if the communication trench is good, and especially if the trench in which they are being used be an old one and the corners of the traverses worn away.

Fig. 10 is a diagrammatic section of another type of trench in use where the ground water level is sufficiently low to allow a depth to be given to the trench sufficient to protect from rifle fire a man a little over six feet high.

Fig. 8.—Diagram to illustrate the difficulty of getting a stretcher round the angles of a trench.

There are, however, many cases, as also many trenches, in which the special stretchers are unusable, so it is common for the problem to be solved by lifting the patient on a blanket or on a stretcher over the parapets or back wall of the trench, and carrying him to the regimental aid post over the intervening ground. Should the trenches happen to lie at the top of an ascent this is a relatively

easy process, but otherwise it can only be carried out after nightfall unless the need for removal is so urgent that the risk must be taken of the patient and his bearers all being killed.

When the patient arrives at the aid post every care is taken to obviate shock as far as possible by the administration of morphine and hot drinks, and by protection from cold. A label is attached to the wounded man briefly

Fig. 9.—A difficult turn.

describing the nature of his injury, and, if some time is likely to elapse before he can be removed out of the firing line altogether, a dose of tetanus antitoxin is given. The medical officer's outfit includes everything necessary for such purposes, as also for the arrest of haemorrhage, the splinting of fractures, and the antiseptic treatment of wounds; but he is not expected or desired to undertake formal operations.

WORK IN THE OPEN.

If the unit to which he is attached be taking part in an advance, the duty of a battalion medical officer usually requires him to wait till the attack has been launched. As

Fig. 10.—Diagrammatic view of a section of a communication trench dug in a part of the country where the subsoil water lies so low that only three layers of sandbags are required to secure protection from rifle fire for a man a little over six feet high. It has a boarded footway at the bottom, and the sides are lined with wire netting supported on spiked stakes. Although in perfect repair, its diameter at the bottom is only about two feet, and at the ground level about four feet.

soon as he sees reason to believe that his battalion is holding its own, but that casualties are occurring, he advances with his men and hunts for a spot where he can establish a regimental aid post.

If the area over which the attack is to be launched is well known because previously occupied or successfully reconnoitred by aeroplane or other observation, the front-line maps prepared for the use of the head quarters of the battalion going into action or occupying the front trenches may indicate to the medical officer where he is likely to find a good place for his regimental aid post. Otherwise he must trust to his own judgement and enterprise, selecting a dip in the ground, an enemy trench, a mine crater, a large shell hole, anything that will serve to protect his wounded from direct fire; in any case it is, if possible, near a road. He starts as soon as possible, not only because his services are needed, but also because the enemy, as soon as the attack has been launched, is likely to try and cut off the arrival of supporting troops by a curtain of shell fire.

His regimental aid-post having been established, and any patients that had been brought to it having been duly treated, the M.O. probably goes to see cases which his orderlies have found, but have not been able to move, or to which his attention is otherwise attracted. For these he does what he can, and if they cannot be moved to the regimental aid-post on account of their condition or the heaviness of the fighting, he tries to collect them into groups, so that they can be found again easily and moved later on. If the area over which his battalion has been fighting is extensive, he perhaps leaves an orderly in charge of the larger groups. The whole of this work is highly dangerous, since, apart from being done under rifle fire, the artillery fire intended to prevent the arrival of supporting troops often affects the neighbourhood in which the M.O. and his men are necessarily working.

Of the men who are not so seriously wounded as to be unable to walk, a good many probably find their way straight to the rear after applying their own field dressings or getting them applied by a comrade. Others make their way to the regimental aid post, and there they remain with the stretcher cases until their wounds have been dressed and the firing slackens sufficiently to enable them to make their way to the rear.

The stretcher cases remain until ambulances come up to fetch them, and unless the fighting is very heavy this process of evacuation will begin very shortly after the action itself; otherwise it is likely to be deferred until nightfall, when in any case a search will be made of the area over which the battalion has been fighting.

FIELD AMBULANCES.

The medical unit lying next behind a regimental aid post is one of those whose functions, though not necessarily their organization, have been considerably augmented or otherwise varied since the war began, in accordance with local requirements.

Originally its main duty was to relieve of their sick and wounded the regimental aid posts, helping them also to clear the field at nightfall or whenever there was a pause in the battle, and treating the cases until it was possible to send them to treatment centres well away from the front. It had to serve in this way simultaneously three or four battalions, all presumed to be in action on an extended front, and the better to fit it for this work a field ambulance was made divisible into three sections, each capable of acting independently, and each again divisible into a stretcher-bearer subdivision for collecting the wounded and a tent subdivision for treatment of the patients.

In several of the localities in which the British army has been fighting during the last three years field ambulances have, no doubt, been working on this plan, but in France the conditions have necessitated a modification of their work and also to some extent of their constitution.

Each remains divisible as before, and each still possesses ten vehicles for the conveyance of wounded, but seven of these are now motor ambulance cars, replacing seven horse-drawn ambulance wagons, and of the nine original medical officers one has been withdrawn. Furthermore, though every A.D.M.S. (senior officer of a division) still has three field ambulances under his direct command for the work of his division, and each of these retains its capacity to work as an independent unit, he sometimes combines forces with the A.D.M.S. of another division, or the field ambulances of all the divisions of an army corps are in effect massed.

The duties they collectively perform are now practically as follows:

1. To collect the sick and wounded from battalions, whether these be actually fighting, serving as supports, or temporarily resting out of the line.

2. To decide what cases must be evacuated, and what shall be treated at the front.

3. To provide permanent treatment for those who fail to pass through the filter thus established, and for the rest temporary treatment pending evacuation.

4. To pursue a like course in respect of local sick, that is to say, cases of illness or injury arising amongst the large number of men who never take part in the actual fighting, but whose presence just in the rear of the fighting line is essential to military operations.

5. To provide for the cleansing at frequent intervals of the persons of the men, the ridding of their clothes from vermin, and their disinfection when epidemic disease is in question.

6. To fill any gaps in the medical establishments of regiments, and to train medical officers and men for this work by sending them for a time to the battalions to see how regimental work is done.

7. To provide temporary assistance when needed to casualty clearing stations

belonging to the army of which the divisional field ambulances form part.

8. To establish advanced operating stations for immediate emergency operations, such as those required in cases of abdominal wounds.

9. To supplement the sanitary work of battalion medical officers when the battalions concerned are located in places which are out of the fighting line but not in direct charge of the sanitary staffs of the army of which the battalions form part.

10. To do for divisions and corps any work for which provision has not yet been made by the army, and which requires for its performance the kind of scientific knowledge medical officers commonly possess.

It may be said, in short, of the British armies in France that their field ambulances are the medical *bonne à tout faire* of the front.

No single field ambulance ever undertakes simultaneously all the duties mentioned, and the way in which they are allocated varies; for the environment of the divisions are not identical, and the senior medical officer of each of the armies and corps on the Western front (subject to orders from a higher authority) exercises his discretion as to the fashion in which he provides for the aggregate medical requirements of the troops in his charge. The experiences of field ambulance medical officers are therefore liable to differ, more especially if the period over which they are compared is relatively short. Commonly, whatever duties have to be performed are taken in turn by each field ambulance available, the period for which it remains employed thereon varying according to circumstances.

If a division is engaged in an active part of the line its evacuation work is usually sufficient to occupy the attention of all its field ambulances, and the same is true of

FIG. 11.—Entrance to a advanced dressing station in the cellar of a partly ruined house.

those of a corps when this is taking part in an advance or definite battle. In such cases the other duties are assigned to the ambulances of reserve or other divisions.

In trench warfare each division engaged generally makes its own arrangements for evacuation, the ambulances belonging to it sometimes acting as independent units, sometimes pooling their resources.

THE ADVANCED DRESSING STATION.

A section of the officers and men available is pushed up to form an advanced dressing station at some place within easy reach of the regimental aid posts of the battalions in action. They choose a place on or close to a road, so that the patients brought down from the battalion aid posts can be sent back rapidly from the advanced dressing station in wheeled vehicles to the place where the field ambulance head quarters or main dressing station has been established.

The advanced dressing station is always exposed to artillery fire, and though sometimes the crypt or cellar of a still standing but more or less wrecked building, such as a church or large school, may be available (Fig. 11) its habitation is, as a rule, merely an enlarged edition of a regimental aid post. (Figs. 12 and 13.) Its equipment and organization likewise resemble that of a regimental aid post, but is larger, because an advanced dressing station is rarely in touch with less than four regimental aid posts. To these it sends, as often as required, sufficient stretcher bearers to clear them of waiting cases, and if any considerable number of men have been left in the trenches till nightfall, it helps to remove them, and retains them till they are fit to be sent further towards the rear.

The way in which it brings down its patients varies in different parts of the line and according to the amount of fighting in progress. Sometimes patients are hand-carried all the way down through a winding communication trench a mile or more long. Sometimes they are carried straight across country, though the latter is possible only at night or when the ground traversed is dead ground—that is, an area which cannot be reached by rifle fire, and not too much hampered by wire entanglements. There are also a few places in which the trenches have an overhead tram-rail, and the wounded men can be transported on a special ambulance trolley suspended from it (Fig. 14), and many areas are provided with tram-lines along which run for the greater part of the distance to be traversed small lorries capable of carrying two or four patients. There are others at which it is possible for the advanced dressing station to clear some at least of its battalion aid posts by sending up a horse ambulance. The means most commonly employed, however, is a wheeled carrier, of which several types are shown in Figs. 15 and 16.

Once arrived at the advanced dressing station the patients are rested, fed and dressed, if necessary, and otherwise prepared to continue their journey, which in most cases will commence as soon as ambulance cars or wagons arrive from the field ambulance head quarters or main dressing station to fetch them.

Advanced Operating Station.

Commonly it is only by night that an advanced dressing station can clear the regimental aid posts with which it is in touch. In the case of an abdominal wound, however, considerations of risk from rifle and shell fire are set aside both at the regimental aid post and the advanced dressing station, and the patient is got down forthwith and sent to the rear in a special ambulance car, kept, if possible, for this purpose in a dug-out near the advanced dressing station, or summoned from the main dressing station or ambulance head quarters by telephone or messenger. The patient goes not to the main dressing station, but either straight to a casualty clearing station or to a field ambulance unit specially arranged for the instant performance of laparotomies, etc. Such a unit is called a corps or advanced operating station, and is established whenever the placing of a casualty clearing station within suitable distance of the part of the line concerned is likely to be delayed.

FIG. 12.—Diagram, drawn from memory, of the entrance end of a small "tube" above-ground advanced dressing station. It is built of curved sheets of corrugated steel surrounded by sandbags and earth, etc.

Varying Conditions.

The ambulance vehicles serving the advanced dressing stations almost always have to traverse roads exposed to shell fire, if not to rifle fire, and efforts are made in various ways to protect their occupants from further injury. When only trench warfare operations are in progress most of the work is done under cover of nightfall, though the depth of the darkness may be disclosed from time to time by the flashing of guns, bursting of shells, and the soaring of rockets. The ambulance transport which comes up to fetch the patients approaches and leaves the advanced dressing stations, as it were, stealthily; and, after anything like a quiet day, two or three trips at most may complete the whole evacuation.

When, however, the division or corps is taking part in an advance or definite battle the reverse is the case. Hour after hour and sometimes for weeks there is a constant inflow of stretcher-borne men, and ambulance vehicles continually arrive to carry away the patients who have received the attention they require; on these occasions the only precautions taken are to keep at a sufficient distance apart so that no single shell shall have the chance of destroying two cars, and to travel sufficiently slowly to avoid jolting the injured more than is inevitable on the shell-pitted roads. It is commonly not until the battle has commenced that an advanced dressing station can take up its position, though the site may have been chosen in advance. As it must always be on a road, so as to ensure rapid evacuation yet never run the risk of impeding the

FIG. 13.—Leading down to a dressing station 30 ft. under the surface.

military work in progress, the choice is often very limited. More likely than not it will be in a deserted trench or enemy dug out, but it is always contrived so that the incoming and outgoing streams of wounded shall not meet, and that the more serious cases can be dressed separately from those that are slight. Provision is also made for cases which may have to be kept for some little time on account of their condition, and for protecting them from gas attacks.

Divisional Collecting Post.

The majority of cases with which it deals are "lyers"—that is to say, men who reach it on stretchers. The

"walkers"—that is to say, men who can find their own way to the rear—are usually shepherded off by patrols in advance of the dressing station to another field ambulance station known as the divisional collecting post, established when a big advance is in progress.

If the area over which the corps is fighting is wide, it usually establishes two advanced dressing stations and two divisional collecting posts in different parts of the field. The field ambulance medical officers at its disposition may be sufficient for this purpose, but in respect of stretcher-bearers it is always short-handed if the fighting be really heavy, consequently on these occasions its own stretcher-bearers are reinforced from various sources.

If the troops in action are very successful and make a prolonged advance, an advanced dressing station may no sooner have established itself to its own satisfaction than it has to make a fresh move to get into close touch with the regimental aid posts.

It will be obvious from what has been said that work in and around advanced dressing stations, whether in trench warfare or in a definite battle, is attended by considerable risk. The fact that it is often exceedingly laborious may not be so apparent. If the fighting is at all heavy, the work as a whole continues without pause for many hours; and while the carriage of a full-grown man over a mile or so of rough ground is never a light task, it becomes absolutely exhausting when at each step the bearers have to drag their feet out of thick mud, and when their clothes, like those of the patient, are soaked with rain.

THE MAIN DRESSING STATION.

The main dressing station is formed by the headquarters of the field ambulance or group of field ambulances responsible for the maintenance of the advanced dressing stations. As it is liable to have to retain the sick and wounded sent down to it for some little time, it is placed sufficiently far behind the advanced dressing station to be out of range of any but heavy artillery fire.

The exact nature of its work depends a good deal on local circumstances, including the character of the fighting in progress. Sometimes it confines itself mainly to administrative work—that is to say, to classifying the cases that arrive, and distributing them for treatment according to their requirements among subsections formed by itself or other units with which it is connected; sometimes it combines this work with actual treatment. However this may be, it always arranges to rest, dry,

warm, and feed the patients that reach it, and for giving them any surgical attention they need before they can safely be sent on elsewhere. It is here, too, that all cases of wounds are examined to see that antitetanus serum has been given.

The first step is necessary because, despite the greatest possible care, the transport of a wounded man from the place where he has fallen to a place as far back as a field ambulance main dressing station must always be very trying, even if his wound be not very severe, and even if his clothes are not, as is commonly the case, soaked with rain and mud. The second step is necessary because in an advance the casualties are certain to be numbered by hundreds, and while many may not need to be sent away from the real front, operations and a period of real rest may be necessary in the cases of many others before their evacuation is possible.

Cases which require evacuation are sent to a railhead hospital or casualty clearing station, and whether their detention at a main dressing station be momentary or prolonged depends—assuming transport to be available—partly on their condition and partly on the distance to be traversed to reach a railhead hospital.

For other cases it provides sometimes by furnishing treatment itself, sometimes by sending the cases on to field ambulances or other medical units set aside for the purpose of special treatment. In every corps area, for instance, if not in every divisional area, provision is made by the field ambulances for the treatment of cases of trifling sickness and injury, or of men who are temporarily exhausted or footsore. Special arrangements are also made for the treatment, without evacuation, of more or less easily cured skin diseases, such as scabies, as also for the

isolation of cases of zymotic disorder and of contacts therewith. Every army, too, has at its service centres which deal with eye cases, dental disorders, and neuroses.

The object throughout is to avoid the unnecessary evacuation of cases that can be treated at the front, for a soldier, once evacuated, is likely, however quick his recovery, to be lost to his unit for a considerable time, since

any patient sent further to the rear than one of the treatment centres mentioned above ceases for the time being to belong to the army in which he had previously been serving, and cannot be restored to it except by passage through a regulated channel. Every patient evacuated from a field ambulance has what is known as a field medical card substituted for his regimental label. It contains particulars as to his name and army status, a

FIG. 14.—The overhead trolley for bringing the wounded through the trenches.

FIG. 15.—A collection of wheeled stretchers and a motor ambulance.

diagnosis of his condition, and details as to whether he has received the requisite prophylactic doses of tetanus antitoxin, and any other information deemed likely to be useful to those who will subsequently treat him.

The accommodation provided for a field ambulance main dressing station varies according to the amount of work that it has to undertake, and may be anything from a village school to a collection of tents. Such accommodation as it possesses is arranged in much the same fashion as at an advanced dressing station, but everything is on a larger scale and the equipment more elaborate. It is thus in a position to undertake formal operations, though it usually limits itself to those essential to a patient's safe evacuation.

The heaviness of the work varies in proportion to that of the units further up the line. If the latter have been hard pressed, many of the cases will reach the field ambulance untouched except for their field dressings, and, even if nothing else be required, special splints may have to be substituted for improvised appliances. On such occasions each corps commonly provides itself with two main dressing stations lying close together, but working independently, one dealing with stretcher cases, the other with "walkers." The patients of the former reach it in ambulance wagons or cars, while those of the latter commonly arrive in char-à-bancs which have been sent up to meet them as far along the road towards the scene of the fighting as these vehicles can be got. This varies, for when a big action is in progress the traffic on all available roads is very heavy, a constant stream of supplies of all kinds being essential to continued fighting.

OTHER FRONT LINE WORK.

When the work of collecting and evacuating the sick and wounded is sufficient to absorb all the personnel of the field ambulances of a division or corps, any other work which they have previously been performing is assigned to those of divisions not in action, or it is provided for in some other way. The general nature of its work is indicated in the list given of the duties commonly performed by field ambulances. When bathing establishments are run as corps or army units, and sometimes even when they are run by single divisions, the arrangements always include the provision of fresh underclothing for every man who has taken a bath.

As commonly not more than ten days elapse between the bathing parades of a battalion most British soldiers change their body linen with comparative frequency, and this counts for a good deal, not only in securing their comfort but in preserving their health. The bathing parades also afford opportunities for picking out men suffering from any form of skin complaint.

Sanitation.

The general sanitation of each army is under the supervision of an expert attached to its Director of Medical Services, while in each division there is a special sanitary section, the officer commanding it acting as sanitary expert, and advising on sanitary matters connected with the division and its component battalions and other units. Each of these sanitary sections has a small staff of non-commissioned officers and men and plenty of equipment, such as disinfecting machines, which accompany the division wherever it goes, while incinerators and the like are rapidly constructed the moment it settles down.

Battalion medical officers draw their supplies of drugs, dressings, etc., from the field ambulances connected with them, and these in their turn from the advanced dépôts of medical stores, one or more of which is to be found in every army area.

MOTOR AMBULANCE CONVOYS.

The field ambulances are responsible for the transport of sick and wounded from the advanced dressing stations to the main dressing stations, and also, but only when working in reserve or resting troop areas, for the conveyance of sick to the casualty clearing stations. The vehicles at their disposal suffice for these purposes, though it may be necessary to supplement them. Should the fighting be heavy and the casualties numerous, they are not intended to transport patients from the main dressing stations to the casualty clearing stations. This is the work of the medical transport units, called motor ambulance convoys, one of which is allotted to every army corps (Fig. 17). It also carries to the ambulance trains the evacuable patients of any advanced hospitals which do not lie immediately alongside a railway line. They are also employed, should pressure on the work of the ambulance trains be severe, in evacuating cases from the casualty clearing stations to the base hospitals by road, and sometimes to transport individual patients whose early arrival at a base is thought advisable, and who can be got there more promptly by road than if detained for the arrival of a hospital train.

Each convoy consists of fifty vehicles, usually divided into two large and one small section. The latter is commonly employed solely for train embarkation, and is then attached to one of the group of casualty clearing stations, and works under the orders of its commanding officer. The other two sections are each under the control of a motor convoy medical officer, who is personally responsible for the safe delivery of all patients loaded on the ambulance cars in his charge. Whenever possible he accompanies his section personally, not only because his attention may be required by a patient, but also in order to regulate the travelling pace. Within limits it is desirable that convoys should get over the ground quickly,

FIG. 16.—A wheeled stretcher, pneumatic tyres.

FIG. 17.—Motor ambulance convoy parked in a village.

and when roads are crowded by ammunition and general supply lorries, all anxious to complete their duties without loss of time, the presence of an officer with the ambulance convoy section ensures it a freer passage than it might otherwise obtain. On the other hand, there may be certain patients for whom a slow travelling pace is desirable throughout, unless the surface of the roads prove excellent—a matter about which there is always uncertainty.

Each motor ambulance car can carry six or eight patients sitting up, or four lying down. To neutralize the tendency to shock exhibited by so many wounded men the vehicles are now generally heated automatically by the exhausts (Fig. 18), and are also provided with hot-water bottles.

The motor ambulance convoys are an outcome of the circumstances of the war in France, and an example of the ingenuity of the Royal Army Medical Corps in promptly adapting its arrangements to the needs from time to time arising. Before the war the Royal Army Medical Corps, in common with the medical services of the armies of all other countries, had to depend for the transport of casualties between advanced formations such as field ambulances, and rearward units such as railroad hospitals, on the use of supply wagons going back empty to the rear. It was the only arrangement feasible at the time, and though admittedly far from ideal, was suitable enough for the small wars in more or less uncivilized

countries to which Great Britain had been accustomed, and not involving any very large number of casualties.

The experience, however, of a few engagements at the beginning of the war showed the Director of Medical Services of the original Expeditionary Force (Sir T.

Woodhouse) that the means in question would not suffice for his needs, while at the same time he found that, in the removal of patients capable of sitting up, ordinary touring cars, of which offers were made to him by various French and other residents in Paris, could be of real assistance. After some of these had been fitted with bodies very like those now used in all motor ambulance work, and others had been sent out from home, he arranged two experimental convoys, which began to work between the Aisne and Paris in the first days of October, 1914. This experiment having proved that motor ambulances could be used with safety for long, rapid transport and over cobbled roads, and not only for short journeys in cities and suburbs, as had previously been supposed, the Director-General of Medical Services (Sir Arthur Sloggett) on his

FIG. 18.—Interior of ambulance car heated by hot-air pipe from exhaust.

arrival in France at the end of October decided to adopt motor ambulance convoys as a definite component of the arrangements of the Royal Army Medical Corps in France. It was a decision of whose wisdom convincing evidence was quickly forthcoming.

(To be continued.)

TREATMENT OF TUBERCULOSIS IN TYRONE.

At a meeting of the co. Tyrone Local Medical Committee held on July 21st, the chairman, Dr. E. C. Thompson, D.L., explained his attitude since his election on the County Insurance Committee, and requested the support of the co. Tyrone doctors. He commented adversely on the general tuberculosis arrangements in Tyrone, and expressed a strong opinion that the present expenditure was largely wasteful, and would continue so until the underlying causes producing the disease were tackled in earnest, and properly and scientifically dealt with. Dr. O'Keefe, the tuberculosis medical officer, had been doing his best endeavouring to administer and put life into a system and procedure which could not be dealt with until the foundations of the whole diseased structure were attacked and demolished. It was worse than useless to spend money in attempting to get rid of a growth which would remain and flourish until the roots were dug up. The soil these roots flourished on was prepared by the bad housing, improper and insufficient food, unsuitable marriages amongst members of diseased families, improperly constructed, ill-ventilated and defective schools, the want of medical inspection of school children, over-indulgence in strong drink, and, most prevalent and deadly of all, the non-provision of suitable buildings in which to house persons suffering from the last stages of pulmonary tuberculosis. Until the real reasons were grasped and dealt with the money and efforts spent were wasteful, dangerous, and deceptive. A professional representative on a committee dealing with such a difficult subject, of which the public knew little or nothing, would fail in his duty if he did not try and advise the committee to adopt practical and sane methods, both of prevention and cure. Great expense was being incurred by the institution of new tuberculosis dispensaries which were entirely unnecessary. The tuberculosis medical officer spent a great part of his time driving over the country, and there was a huge outlay on the rent of the new dispensaries, unnecessary nurses, drugs, etc. It would be far better to work

through the dispensary doctors; without their active help all the efforts now made would be largely useless. No man could possibly get into touch with the whole population of Tyrone. The dispensary doctors knew almost intimately every family in their respective districts, and it would be easy for them to hunt up cases of tuberculosis, and, when required in doubtful cases, call in the tuberculosis medical officer. Dr. Patrick, Dr. Lyle, Dr. Bradley, and Dr. Murnaghan having expressed views in substantial agreement with those of the chairman, the following resolutions were unanimously passed:

That we recommend the Tyrone County Council to take the following matters into consideration: (1) Notification of tuberculosis (early cases) and isolation of advanced cases. (2) Improvement of schools and proper provision for feeding of children; medical inspection of schools and children. (3) Proper housing of the working classes, and improvement of the houses of the middle farming class. (4) The Act to be administered through the dispensary doctors and the other medical attendants, using the present dispensary houses and doctors' surgeries for the attendance of patients; notification of cases through dispensary doctors and other medical attendants. (5) Slaughter of infected cattle.

That this committee is of opinion that if patients are to have sanatorium benefit the Tyrone Sanatorium should be opened as soon as possible.

That we endorse the public statements made by Dr. Thompson on the tuberculosis question, and are of the opinion that he deserves the gratitude of the public for his efforts to improve the procedure under the scheme; that it is quite clear that Dr. Thompson's criticisms have been directed against the inefficiency of the tuberculosis portion of the scheme, and not against any individual.

THE object of the Association for the Study of Internal Secretions, founded at Detroit in 1916, is to co-ordinate the work of experimenters in all parts of the world who are especially interested in the study of internal secretions, the ductless glands, and organotherapy. It publishes monthly a small periodical entitled *The Link*, containing information and correspondence; a quarterly bulletin entitled *Endocrinology* is also issued. The Secretary is Dr. Henry R. Harrower, Glendale, California, U.S.A.

British Medical Journal.

SATURDAY, AUGUST 18TH, 1917.

THE SCHOOLS AND THEIR MEDICAL SERVICE.

THE President of the Board of Education, in the lucid speech in which he introduced the new Education Bill into the House of Commons on August 10th, defined its main aim to be "to secure for every boy and girl an elementary school life, up to the age of 14 years, which shall be unimpeded by the competing claims of industry." It does not deal with university, professional, or technical education, but it is a sign of the trend of expert opinion that it proposes to give to the continuation schools for young persons from 16 to 18 years of age a "vocational bias."

Mr. Fisher was careful to make plain that by school life was to be understood a balanced training of mind and body, indeed his insistence all through on the obligation on the country to safeguard the health and improve the physical standard as well as to inform and develop the intellect of children growing in mind and body, was the most striking and in principle the most novel point of his speech. The evidence upon which he rested his case was drawn largely from the facts ascertained by the school medical service, the establishment of which in 1907 Mr. Fisher described as "one of the great events in our social history." Its work has shown how much the value of our educational system is impaired by the low physical conditions of a vast number of children, and how imperative is the necessity of raising the general standard of physical health among the children of the poor. The evil effects of premature or excessive employment have been traced by the school medical service in diminished height and weight, in curvature of the spine, in cardiac affections, and in deficiency of the senses, especially the sense of vision, and in the bad dentition of our working classes. The bill provides for the abolition of the half-time system under which some 30,000 children in Lancashire and Yorkshire between the ages of 12 and 14 are permitted to divide their working day between the factory and the school, and for a stricter regulation of the employment of school children out of school hours. They may now be employed for three hours before the school opens, and for some hours after it closes. The bill proposes to make universal the provision, already contained in by-laws of some large municipalities, that no child under 12 shall be employed for profit. It proposes to allow a child between 12 and 14 to be employed between 6 a.m. and 8 p.m. on Saturdays and during school holidays, but, recognizing that this concession may be abused, to give power to the local education authority, if satisfied, on the report of the school medical officer or otherwise, that the child is being employed in such a way as to be prejudicial to health or education, to forbid or regulate the employment; it would have power also to decide to continue the education in the elementary schools either of the boys or the girls in the area, or of boys or girls following particular occupations, up to the age of 15.

The intention is that the normal school age shall be 5 to 14 without any exceptions between those ages. To meet the case of the earlier ages it is proposed to

encourage the establishment of nursery schools for children under 5, and to empower local education authorities to raise the age at which the normal instruction in elementary schools shall begin to 6. We believe this raising of the age of commencement of normal instruction to be an important move in the right direction. The enormous amount a child has to learn during the first five or six years of its life is not always realized; it has to learn to recognize external objects and their qualities as well as how to use its own limbs—lessons best learnt by playing with other children—and Mr. Fisher recognizes that wherever the home is good the child should be encouraged to stay with the mother. It has also to learn its native tongue. During these years the brain and nervous system are growing rapidly, new channels for the outgo of nervous energy are being formed, and the several paths established linked up. As Mr. Fisher said, at 4 or 5 years of age sleep and play are far more important than letters, and it may be assumed that this will be the governing principle in the conduct of nursery schools. Attendance at such schools would be voluntary, but they would be aided from the rates, and it is intended that they should often be open-air schools.

Another novel feature of the bill is a proposal to require any young person no longer under obligation to attend a public elementary school to attend a special continuation school for a period of 320 hours in a year, or the equivalent of eight hours a week for forty weeks. This compulsory provision would not apply to a young person who had received suitable full-time instruction up to the age of 16, or had passed the matriculation examination of a university of the United Kingdom, or an equivalent examination, or was shown to be unsuitable or deficient for part-time instruction. These continuation schools would be provided either by the local education authority, or under its direction, as, for instance, by manufacturers in their works. The continuation school hours would be by day, and not on a Sunday or holiday, so that young persons attending would be liberated from industrial toil for three half-days a week during forty weeks, two half-days being spent in the continuation school and one as a half-holiday. This proposal is likely to excite some opposition on general industrial grounds, although Mr. Fisher recognizes that different types of schools will be required in different areas, and in particular the rural areas, but we should have liked him to have defined the vocational bias he desires such schools to have more clearly, in relation to agriculture in particular. The direction in which he is moving was shown by the expression of his hope that boys and girls attending these continuation schools would more readily join the scouts or girl guides or some other associations carrying with them intellectual and social advantages. It is a great gain to have a Minister of Education declaring that it is important to secure in such schools a physical minimum for girls and boys. He contrasted this scheme with any form of military conscription, and urged that it was not open to the objections to which any such system is necessarily exposed.

Towards the conclusion of his speech he insisted again on the necessity of taking advantage of this opportunity to assist physical education in every possible way. Physical training, already a part of the work of elementary schools, should be extended to the continuation school, and should be given in every one of them. Further, the bill would empower local education authorities to supply and maintain playing fields, school baths or school game centres, and equipment for physical training. It would also

extend their powers and duties with regard to medical inspection in elementary and secondary schools and in continuation schools.

Sir Clifford Allbutt said very truly and shrewdly a little time ago that the British boy's bent was to do things, not to be talked to about them, and the bent of the British artisan when a new idea in his own line was presented to him to go to his bench and see whether it would work; both love to look on the concrete side and to acquire dexterity. Most of the things the British boy wants to do are out-of-door things, and we may be glad that it is so, and that the Minister recognizes that any sound scheme of education must have regard to the cultivation of the body as well as of the mind. It is a very old story, this, of the sound mind in the sound body. That it is now beginning to be wisely applied to the industrial classes, as it has long been applied in the great public schools and universities, we owe to the labours of countless pioneers during the last three or four generations, brought to fruition through the labours of medical men and women in and out of the school medical service, inspired and directed by the medical officer to the Board of Education. Sir George Newman had a difficult task to persuade not only the public but those of his own specialized department. He is to be congratulated on the results so far obtained; they are very notable, and contain promise of even better things.

ANCIENT WALES.

It is no exaggeration to say that a paper which has just appeared in the *Transactions* of the Honourable Society of Cymmrodorion¹ is the beginning of a new chapter in our knowledge of ancient Wales. Its author, Professor H. J. Fleure, of University College, Aberystwyth, has invented and applied what may be described as a new method of anthropological inquiry. It is not a new idea to suppose that there may be hidden away in upland valleys and moorland recesses pure samples of the races and people who have invaded Britain and settled in it; that is an old idea. Professor Fleure's merit lies in the fact that he has put this basal idea to the test of experiment. He selected as the scene of his inquiry those Welsh counties which lie within reach of Aberystwyth. For many years before the war he and Mr. T. C. James spent every spare day they could steal from their duties in visiting the sequestered nooks of Wales and in measuring and charting the anthropological characters of their inhabitants. Their aim was to prepare an anthropological map of rural Wales. By the ingenious use of a series of hieroglyphic signs they were able to represent on their maps the physical characteristics of the population in each river valley, coastal area, and moorland expanse—the first real anthropological survey ever carried out.

Having prepared such a map, Professor Fleure commenced to investigate and interpret the facts thus brought to light. He found, for example, that along the valley of the Teify, which forms the boundary of Cardiganshire on the south-east, and also in the valleys of Denbigh and Glamorgan, the prevailing type—short in stature, long-headed, dark-haired—was similar in characters to the people who buried in long barrows, the prevailing British type of the neolithic period. In the moorland district of Pliulimmon, in the north-eastern part of Cardiganshire, he found a nest of people whose characters are believed to be reminiscent of the British of the

paleolithic period. It was in the coastal areas that Professor Fleure made his most important discovery—the existence of a dark-haired, round-headed type, a characteristic Welsh type, which he traces to Brittany, and which he supposes may be ultimately followed to the Mediterranean.

The results of these inquiries, so far as they relate to the various anthropological type of Welshmen, are given in full in a recent number of the *Journal* of the Royal Anthropological Institute.² In his paper to the Cymmrodorion Professor Fleure marshals the evidence derived from other lines of inquiry—from a survey of the distribution of ancient megalithic structures, stone implements, bronze instruments, and ancient gold ornaments, folk-tales and traditions, the distribution of Welsh dialects, and of place-names—to see what light they would throw on the time and manner in which the various racial types have come to Wales. As yet his deductions are tentative, but it is very clear that as those methods are pursued and perfected, the time will come when problems which now seem beyond our powers will be fully solved. There can be no doubt that those who have sought to unravel the ancient history of our country have kept their eyes too fixedly on the eastern and southern coasts. All great racial movements were pictured as coming from the east, with a crushing of the ancient population towards the western seaboard. Irish anthropologists have gone to the opposite extreme; to them there was only one route—the sea route leading from Spain and Brittany through the Irish Sea to Scandinavia. For Professor Fleure this is the “west coast route,” and as he passes in review the various lines of evidence the student cannot fail to agree with him that it was by this route that most of the ancient races and ancient civilizations and languages reached Wales. The recognition of two ancient portals of access to Great Britain and Ireland, portals of equal degrees of importance, gives a clue to many circumstances we could not explain before, and perhaps the greatest service Professor Fleure has now rendered is the placing of the west route in its right perspective as a portal of access to Britain.

TERRITORIAL AND TEMPORARY OFFICERS R.A.M.C.

We understand that Sir Alfred Keogh has in contemplation the establishment in the office of the Director-General in England of a branch to deal with questions directly affecting territorial and temporary medical officers. It will be able to collect and collate information on the many problems raised by the incorporation in the Army Medical Service of so large a number of civilian practitioners. The fact that they now constitute some eleven-twelfths of the service is in itself sufficient to justify the new departure. The country has to face the fact that in every direction the drain upon its man-power has become severe, and not least on the medical man-power. The branch will also be in a position to advise on the selection of officers for particular types of work for which they are specially qualified by character and experience. It is, we understand, intended that the staff of the branch shall include a territorial and a temporary officer having recent experience of war conditions. We believe that this announcement will cause a widespread feeling of satisfaction. Territorial medical officers, and the officers of the Special Reserve, as well as a large proportion of officers holding temporary commissions R.A.M.C., are volunteers who have given the best possible proof of their

¹ *Ancient Wales—Anthropological Evidence.* By H. J. Fleure, D.Sc., Professor of the University College of Wales, Aberystwyth. *Transactions of the Honourable Society of Cymmrodorion.* Session 1915-16, pp. 75-164.

patriotism and of loyalty to their profession. There has been a feeling among many of them that, to use a current phrase, they were nobody's children, and that there was no one to whom they could carry their difficulties and their suggestions. If, as we hope and anticipate, the new branch supplies this want, it will be able to do not a little for the contentment of the services, and indirectly, therefore, for the welfare of the country and the successful prosecution of the war.

ARMY MEDICAL ECONOMIES.

MR. MACPHERSON, in the course of his reply in the discussion on the Army Medical Vote, reported elsewhere in this issue, said that the War Office was doing everything possible to meet the civilian needs, and that the Central Medical War Committee, a body appointed to consider the claims of the military and civil population, had done its work very well. The primary duty of the War Office was to respond to the demands of the commands in the various theatres of war for medical officers to serve the needs of the fighting men at the front. He admitted that there were many hard cases, such as those mentioned by Sir Garrod Thomas, where the civil population had been hard put to it to meet civilian needs, and he repeated the statement that the Secretary of State for War had determined to send a committee of distinguished men to France—which is the main theatre of war—to ascertain whether there is any misuse of the services of medical men serving there. It is hoped that the names of the members of the committee will be announced in the course of a few days, but it is to be understood that, as at present arranged, the instructions to the committee will be to advise whether medical establishments in France can be reduced without diminishing efficiency. As will be seen by the report published in the SUPPLEMENT, p. 48, the joint meeting of the Committee of Reference of the Royal Colleges in England and the Central Medical War Committee, on August 15th, expressed the desire that the inquiry should be extended to include the working of the service in this country.

A MAIDEN SUCCESS.

OUR Parliamentary Correspondent writes that in an experience of fifteen years he has never known a maiden speech which so quietly and impressively engaged the attention of the House of Commons as that of Sir Watson Cheyne on the Army Medical Vote this week. The assembly, it is true, was small, as members of Parliament are not wildly enthusiastic over the agitation on behalf of bonesetters, but it could easily have been critical, or it might in the general circumstances of fatigue have shown itself weary. Instead, Sir Watson held it under a spell. He was in the naval uniform of his rank as surgeon-general with consultative duties for the navy, and he spoke from a seat immediately behind the Treasury bench. His manner was charming. He did not patronize, nor did he apologize—except once when he found himself about to quote something that was amusing, and brought an instant laugh by an expression of regret that he should so commit himself where every one had the reputation of being so serious. Somebody thought he said "dull," but that was quite a mistake. In a very short time those around him lent themselves to the suggestion of a clinic, and it was symptomatic that the only interruption was the somewhat plaintive appeal from a member below the gangway that Sir Watson would speak louder. A fear on his part (after a lucid little dissertation on the art of bone-setting) that he was drifting into a lecture on surgery, brought the cry of "Go on." This from a more than ordinarily jaded house in the middle of August was compliment indeed. But the most interesting moments were those when he was presenting to the imagination, dispassionately and coldly as a scientist, the risks that were run by those who submitted to a bonesetter with restricted

knowledge. Fortunately Mr. Hodge, who was so proud of his cure, had had the assurance from Sir Watson that Mr. Barker was a distinguished and successful operator, but it was a little awkward for the Labour Minister immediately below to hear the matter treated in this grim fashion. He heard how, after operations by some bonesetters, tuberculous disease had spread, and how after operations by others a local tumour had been distributed through the body. He heard how in consequence Sir Watson had more than once been obliged to amputate limbs of sufferers. Mr. Hodge with one hand upon his knee (presumably the knee) was a study during the story. And Sir Watson did not seem to know the effect he was producing.

CARE OF THE BLIND.

THE Departmental Committee on the Welfare of the Blind appointed in May, 1914, under the chairmanship of Mr. Hayes Fisher, M.P., has this week presented its report. It was instructed "to consider the present condition of the blind in the United Kingdom, and the means available for (a) their industrial or professional training, and (b) their assistance." The report recommends the establishment of a special Government department to secure central control, organization and assistance for existing voluntary agencies, and additional assistance for the blind. It recommends that the new department should be set up in the Local Government Board, but should form a part of the Ministry of Health whenever such a ministry is created. It advises that the department should be administered under the immediate guidance of an Advisory Committee of persons associated with the care of the blind, and that the chairman of this committee should be the Parliamentary Secretary of the office in which the new department is established. This Advisory Committee should consist of seven members, of which the vice-chairman and one member might be paid. All matters of policy should be referred to this committee and all executive functions exercised by the department in accordance with the recommendations of the Advisory Committee. The following uniform definition of blindness is recommended: "Blindness means too blind to perform work for which eyesight is essential." With regard to the causes of blindness, it is stated that ophthalmia neonatorum is the cause of 10 per cent., and it is recommended that uniform and more effectual notification of the disease and the immediate treatment of all cases should be secured. It is also recommended that the provision and wearing of goggles in dangerous occupations should be made more widely obligatory. A series of recommendations are made with regard to the elementary education of blind children and as to the professional and industrial training of blind persons. The committee finds that, except, perhaps, in the case of blind girls, the present accommodation for professional training appears to be adequate, and the accommodation for industrial training not materially deficient. At present in England many more persons receive industrial training than can be afterwards employed in the available workshops. It advises that some three thousand additional places are urgently required, the estimated cost being from £100 to £175 each. This, the only capital expenditure on which the new department should embark, would involve a sum of £500,000. The annual expenditure is estimated at approximately £250,000, which would apparently include an increase in the number and amount of pensions for the blind. The committee praises the arrangements for training provided at St. Dunstan's Hostel, and the work of the National Institute of the Blind to secure their welfare after leaving the hostel, but states that the institute is handicapped by want of funds. At St. Dunstan's the largest number of men learn cobbling; they can learn to sole and heel a pair of boots in six or seven months, and can afterwards make good earnings. The men who learnt cobbling were also taught mat-making as an alternative

occupation; basket-making, joinery, and shorthand writing were also taught, and the men who took up massage had been uniformly successful in passing the severe examinations of the Incorporated Society of Trained Masseurs; wherever possible, however, a man was returned to his original occupation. The report is signed by all the members, but reservations on various points of detail are made by several of them.

ECONOMY IN PRESCRIPTIONS.

We referred last week to the action of the General Medical Council in withdrawing from the *British Pharmacopoeia* a considerable number of galenical preparations containing sugar and glycerin. The committee appointed by the Home Office in 1914 to deal with the matter of economy in the use of drugs is issuing this week to every member of the medical profession a memorandum pointing out the urgency of strict economy in the medicinal use of glycerin and sugar, and preparations containing them. Since the issue by the same committee of a memorandum in January last the position has become more stringent. Glycerin for medicinal purposes is no longer being manufactured, so that the dependence is entirely upon existing stocks. These, it is believed, will be sufficient, if due economy is practised. The memorandum makes suggestions as to the use of substitutes for glycerin and sugar or syrup, prescribed as such, and for preparations formerly official but now non-official containing these substances, and points out the need for refraining as far as possible from using those drugs containing glycerin and sugar which remain official.

THE ROYAL SOCIETY OF MEDICINE.

THE annual report of the Royal Society of Medicine for the session 1916-17 shows that, like other similar bodies, it has suffered through the war; it has, however, on the whole, well maintained its position, both with regard to numbers and to finance. Sixty-eight fellows and four members were elected during the session, and the numbers now are respectively 2,824 and 739. The punctuality in the publication of papers in the *Proceedings* of the society has been impeded by the War Office censorship, but the value and bulk of the publication has not been diminished. On the resignation of the first editor, the council accepted the offer of Mr. J. Y. W. MacAlister, the secretary of the society, to act also as editor without any addition to his salary. He has now performed this self-imposed task for three years to the satisfaction of all, and has added to his labours by introducing notes on books. The meeting adopted by acclamation a cordial vote of congratulation and thanks to Mr. MacAlister on the completion of his thirty years' of service to the society, accompanied by an expression of an earnest hope that his health might permit him to continue his work for many years to come. The report stated that the special work carried on at the Marcus Beck Laboratory for the Medical Research Committee had been brought to a close early in the year, and that the several departments of the laboratory were thus again available for the private work of fellows. The report of the librarian stated that the number of readers during the year was 9,219 and the number of books borrowed 5,127. The number of books and pamphlets added during the year was 4,477; of these, 3,398 were presented, 126 new books as distinguished from periodicals were purchased, and 153 were received gratis for review in the *Proceedings*.

THREATENED SHORTAGE OF RUBBER OPERATING GLOVES.

THE attention of the British Medical Association has been called to the fact that, owing to the action of the Board of Trade in prohibiting the importation of rubber operating gloves, there is likely to be a serious shortage unless the restrictions are removed or diminished. It appears that

the majority of gloves used by surgeons in this country in the past have been imported from America. The demands of the medical services of the army and navy for gloves are now very large, and are being met, it would appear, mainly under special licences to import. It seems that manufacturers in this country have not been able to meet the demands of the army, which take precedence of those of the civil hospitals, so that the case of the latter is parlous. A memorandum has been addressed to the Board of Trade by the British Medical Association urging the issue of licences permitting the importation of supplies adequate to the needs of the civil community. We understand that the Board is prepared to make a concession.

HOSPITAL SHIPS.

We are able to confirm the announcement that, as the result of representations made by the Spanish Government in Berlin, London, and Paris, the German Government has agreed to a safe passage for hospital ships on condition that a Spanish naval officer is on board and guarantees that the vessel is used only for the transport of sick and wounded. The French and British Governments have agreed to the arrangement, and eleven Spanish naval officers, who will be posted to hospital ships under the agreement, left Madrid for French ports about a week ago. The guarantee to be given by the Spanish officers will not involve any departure from the invariable practice of British hospital ships, although the German Government has characteristically professed to believe the contrary.

Medical Notes in Parliament.

Army Medical Vote.

MANIPULATIVE TREATMENT.

THE Army Medical Vote, which was taken in the House of Commons on August 14th, gave Mr. Peto an opportunity of raising a debate on the subject of "manipulative treatment" of soldiers in the army. There was not a large attendance.

Mr. Peto, in the first instance, recapitulated the nature of the offer made by Mr. H. A. Barker and the objection taken by the War Office authorities to the employment of any unqualified practitioner. He next touched on the history of bonesetting, and said that for seventy years the medical profession had stopped its ears and been content to throw stones and injurious epithets at the very few manipulative surgeons. Coming to the immediate controversy, Mr. Peto referred to the suggestion that bone-setting should be legalized by Royal Charter, and that a four or five years' course should be established, as in America. He also read the opinion (already published) given by three legal members of the House (Sir John Simon, Mr. Butcher, and Mr. Pollock) that there was no ground for holding that if the War Office or Admiralty arranged for a disabled soldier to be treated by an unregistered practitioner, such as Mr. Barker, the law was thereby broken or disregarded. That opinion, Mr. Peto reminded the House, had been referred to the law officers of the Crown, and they had held that, subject to conditions, the War Office might lawfully take certain action. They had advised, however, that the opinion of the General Medical Council should be obtained before orders were given with a view to such action. Nothing had been heard of any orders being given. A deputation of sixty members which waited upon the War Secretary on May 4th received the usual official answer that told really nothing whatever. They had a little debate with Sir Alfred Keogh and other eminent gentlemen there, but did not get much satisfaction. The question was purely whether the General Medical Council was going to put such opposition in the way of what he and his friends wanted that the War Office would not think it worth while to use their authority. Mr. Peto then quoted several cases successfully treated by Mr. Barker, mentioning them chiefly, he said, to show the attitude of the medical profession. Some of these have already been published. One of the most recent was the case of Mr. Hodge, the Minister

for Labour. Mr. Hodge stated how he was half-carried to the surgery, but in half an hour walked out without aid of any kind. In conclusion, Mr. Peto asked the Under Secretary for War to say that he had thought out some method by which, without going into any controversial questions or offending medical etiquette, he could do the practical thing—place Mr. Barker and the injured soldiers in contact with one another.

Sir John Simon said that if the War Office thought fit to authorize a soldier to consult one of these unqualified medical practitioners, it might be a wise or unwise thing to do, but it would be perfectly legal. If an officer might avail of such services, the men in the ranks ought to be allowed to take advantage of them also. He thought a case had been made out for the War Office to permit, in a proper case, an ordinary soldier to avail himself of assistance gratuitously offered. If in any given case the War Office authorized and ordered that to be done he could not believe that responsible authorities in the medical profession would visit with punishment any member of their body who took such a course. If that were done something would be heard about it in the law courts, and he was certain that whether it was treated in the law courts or not, it would produce a serious impression on the minds of the public, who would feel that if the Army Council thought the course one to be followed those who served it could not be visited with pains and penalties.

Sir Watson Cheyne, who qualified as member for Edinburgh and St. Andrews Universities on the previous day, said he should not have dreamt of making a maiden speech so soon but for the nature of the subject before the House. He also mentioned, by way of preface, that he had decided to drop private practice from the time he became a member of Parliament, as he wished to speak with complete independence from suspicion of personal gain. He had asked to be allowed to continue his work in the Royal Naval Medical Service, but that was all. Sir Watson went on to say he was in rather a fog as to what proposition had been made in regard to Mr. Barker. Sometime ago gossip had it that he was to be offered a commission and that it was refused. Nothing was said about a commission to-day. Sir Watson said his point was that if something were done for one particular bonesetter it was difficult to see how others could be kept out. He did not dispute the excellence of Mr. Barker's work, but if he were accepted, the Army Medical Service would be flooded with a set of irregular practitioners who were absolutely incompetent. If bonesetters were admitted, where was the thing to stop? Were they to refuse faith healers who gave wonderful accounts of their work? Then there were cancer curers, and plenty of herbalists and all sorts of unqualified persons who had asked to come in. His own experience of bonesetters, as a rule, was that they were not educated for their job. They were usually brought up in places where a considerable number of accidents occurred, and had acquired a reputation for facility in dealing with them. He did not say that there were not some men who, having become bonesetters, had set to work to try to learn something about bones and joints; but the average bonesetter did not. The bonesetter had only one diagnosis—dislocation—and only one method of treatment, and that was to wrench and twist the limb. The human frame was a very delicate organization. It should not be meddled with by people who did not know it as intimately as it was possible to know it after years of study. In this country any man who said he was a bonesetter could be employed, and would have a *clientèle* who believed very strongly in him. Would any business man like to employ a man who had never spent any time in learning that particular business, but had in some way or other acquired a reputation for knowing something about it? It should be necessary to be convinced that he was really good at his work before he was taken. Sir Watson, after giving an instance of what appeared to be to him a very interesting example of want of knowledge on the part of a very distinguished bonesetter in London, said that in spite of want of knowledge on the part of the great majority of bonesetters, they did often produce marvellous cures, and it was a great puzzle for a long time to know how these cures were brought about. They themselves spoke of a dislocation which they reduced, but it was quite

clear that in many cases this was not so. It was only after long study that what had occurred was really explained. It happened often that if a joint was injured a certain amount of inflammation occurred in the lining membrane of the joint, and if it was kept at rest sufficiently long the two folds of the lining membrane stuck together, and sometimes stuck so firmly together that in the course of time the joint could not be worked; not only did the two bones stick together but the muscles and other structures, and the patient got a stiff joint. What happened when the bonesetter operated on what he thought was a dislocation was that he tore through these adhesions and released the joint. Developments of that kind occurred often in former days, and now the surgeon was on the alert in the case of all injuries against such developments; it was chiefly with a view of avoiding these adhesions that massage came into being. They had learnt why it was that these bonesetters sometimes succeeded, but there was no reason why they should set them to treat our wounded, seeing they knew so little about the subject; a competent surgeon could do all that was necessary, though, of course, some were more timid than others. Adhesions might begin in twenty-four hours, but it was not difficult to break them down; after three or four days it was more difficult, and after a month it might need a strong athletic man to break them down, but the result was safer. Another explanation of success of the bonesetter was that he usually did not get the case until many months after, until the adhesions were converted into cords which could be snapped across and the joint freed at once. Nowadays this was so well known that any good surgeon would do what was wanted much more safely and quite as well as the bonesetter. There were certain dangers in connexion with these cases: it might happen as the result of a sprain or slight injury of the joint that disease was set up in the adhesion—for instance, a patient with a tendency to tuberculosis might get a tuberculous cyst in connexion with the injured joint; probably such a joint would get well with careful attention, but, if a bonesetter broke it down with violence, it might set the tubercle growing with rapidity and utterly spoil the joint. He had seen many such cases and more than once had had to amputate. A still more tragic thing was that a tumour sometimes developed in the bone, and he had known cases in which the bonesetter, still thinking it was a case of dislocation, had violently broken up the part, and the disease, which was local, had then spread throughout the whole body. Turning then to cases of dislocation of the cartilage, he said that it might be due not only to injury but to three or four other causes. When it was really a case of dislocation of a cartilage manipulation might give great success; it was necessary, however, to exercise great care in diagnosis. In soldiers it was not usually a case of loose cartilage, but terrible fractures and terrible breaking up of the joint. He had not heard that bonesetters claimed any skill in treating wounds; the treatment of wounds was the whole science of the business of the surgeon among soldiers. Sepsis getting into wounds was the trouble, and to avoid sepsis was a difficult problem not yet fully solved. Was the bonesetter to be allowed to put his dirty fingers into a wound? The whole matter required very careful consideration. Because a man had had success in one particular and small department of surgery the whole of the country's existing system should not be upset, and an immense amount of unnecessary ill-feeling created.

Mr. Noel Buxton spoke of the charm of the speech of Sir Watson Cheyne, and hoped the House would not be carried away by it. It was not accurate to say bonesetters did not spend time in training. The osteopaths passed through a course of study of four years, with not less but more time on anatomy than was given in the regular school. Mr. Buxton added personal testimony to the services which had been rendered by osteopaths.

THE SHORTAGE OF DOCTORS.

Sir Garrod Thomas, in a maiden speech, referred to the medical arrangements generally in the country. His object, he said, was not to find fault, but to set out certain facts and make suggestions. He had only admiration for the way in which the medical necessities of the country had been met when the demands came with such suddenness and on such a colossal scale. They were greatly

indebted to the Director-General of the Army Medical Service. The mistakes which had been made in his department were in the main due to his eagerness to do his very best for it. But he thought that even the Director-General would have been better advised if he had more often consulted the Advisory Board. The fact that the House had to remember was that the supply of medical talent was necessarily limited—the number was about 15,000. The medical man was a plant of very slow growth. The question arose how most economically to make use of that material for the general weal—for the army certainly, but having some regard also to the requirements of the civil population. He agreed with what had been done with regard to Salonica, Mesopotamia, Egypt, and Palestine. The men were there ready to do work, and the less they had to do the better it was. In regard to France the matter was different. The journey was short, and it was a waste of valuable material to keep men for months there working only one, two, or three hours a day. It was a great waste also to employ medical men to do jobs which could be done very well by men without medical training. One man wrote him that he joined the Royal Army Medical Corps in July, 1916. He had at most about two hours' work a day until the battle of Arras—in April, 1917. He had one hard week's work, and in June he had another three weeks' moderately hard work. Since then he had been transferred to a cavalry field ambulance, where he had no medical work to do at all. This case was not exceptional. He knew of three motor ambulance convoys, each with two medical officers who were doing no medical work whatever. Sir Garrod said that another correspondent had informed him that the amount of work he had done requiring medical knowledge during eighteen months in France could be done in a few hours. A third wrote that he had done only a few days' real medical work in two years. In further illustration of waste, Sir Garrod said that during March of this year it was arranged that an extra 1,000-bed unit in France should be staffed by one of the London military hospitals. Specialists, other doctors, nurses and orderlies left for France at the end of March. They had to wait three months, some of them unemployed, before the hospital was ready. Having expressed the opinion that there was also waste in employing so many medical men in the procedure for discharging wounded soldiers, Sir Garrod said it also appeared that many medical officers had their time wholly, or nearly, taken up with clerical work. A well-known physician of a great London hospital said that he was employed doing scarcely anything but clerical work which could be done very well by non-medical officers. He believed that some other cases of waste occurred through what he called "misfits"—that was, through not considering sufficiently to what branch of the profession a medical man had given his life. There should be an inquiry at which all men could speak frankly and fearlessly, and at which the balance could be held evenly between the needs of the military and the civil population. He knew of one cluster of villages, with a population of eleven or twelve thousand, that had five medical men before the war; early in the war three left, and now the junior of the two left had been told to be ready to join the forces, leaving the population with only one medical man; he had two big collieries to look after, and a hospital to which he usually sent his patients was so understaffed that they were unable to cope with their work. Sir Garrod, in conclusion, urged that the matter upon which he had dwelt should be taken up promptly.

Major David Davies afterwards submitted in a vigorous speech that the Director-General should be made a member of the Army Council. He pointed out that before the Esher Report on the reorganization of the War Office was adopted the Director-General had direct access to the War Secretary and was directly responsible to him. After the report, the Director-General was put under the control of the Adjutant-General, and that he regarded as a most retrograde change. After the Crimean war, when great reforms were brought about in the Medical Department of the War Office, the principle was insisted upon that the Director-General of Medical Service should be directly responsible to the War Secretary and through him to the House. For that position to be restored to this officer would, the speaker thought, be the beginning of all reforms in the Army Medical Service, and without it no real good

could be accomplished. He quoted a letter by Lord Esher to the *Times*, on February 5th, in which, in the light of events, Lord Esher repudiated the conclusions of his own committee and appealed to Lord Derby to strengthen the Army Council by placing upon it the D.G.M.S., holding that thus would the work of Sir Alfred Keogh be happily recognized to the infinite advantage of the sick and wounded of to-day and to-morrow. Major Davies asked the House to consider how other countries dealt with this matter. In France one of the Under Secretaries for War was the head of the Army Medical Department, and he was a very prominent medical scientist. In the United States General Gorgas, who was responsible for the whole of the sanitation in connexion with the building of the Panama Canal in the Canal zone, was now at the head of the Army Medical Service of that country, and had direct access to the War Secretary. The same thing also applied in the case of the Russian Government. Apparently, ours was the only country where the importance of the medical profession, of scientific medicine and of all that implied, was not recognized. We were the only country where the doctors and the medical profession were not given their proper place in the organization of the army. He should like to know whether the Director-General, before the expeditions to Salonica, to the Dardanelles, and to Mesopotamia, was consulted. Were our great scientists in tropical medicine consulted before these military operations were undertaken? The medical faculty ought to be given its proper place in the organization of military operations, and in that connexion he urged that the high administrative posts should be opened up to the civilian members of the medical profession.

REPLY FOR THE WAR OFFICE.

Mr. Macpherson, taking up first the question of army medical reorganization as raised by Major Davies, recalled that the Esher Committee unanimously concluded that it was not proper that the Director-General of Army Medical Service should be a member of the Army Council. He acknowledged that this conclusion was reached many years ago, and recognized what Lord Esher had since written in an opposite sense. But he asked the House to remember that the War Secretary was always ready to see the Director-General at any moment when he had business of urgent importance to discuss with him. Mr. Macpherson was unable to say whether a new committee, if appointed, would consider the matter afresh, but he promised to bring it under the notice of Lord Derby. He came next to the complaint of Sir Garrod Thomas as to the misuse of the services of medical men at the front. He reminded the House that there was a Central Medical War Committee, composed of representatives of the civilian profession, who, together with the War Office, considered the claims of the military and civil population. If there was a claim between the civilian population and the soldiers fighting at the front, the House, he was sure, would not hesitate to say that the claim of the soldier should first be met. Lord Derby, however, had said that he would send a committee of distinguished men—he did not care who appointed them—to inquire in France whether there was a misuse of medical men, distinguished or otherwise. This would be done immediately. The House should remember that the old theory of the medical man in the army was that his primary qualification should be that he was a qualified doctor, but the other qualification was (and it must be so in the economy of any regiment) that any officer in a regiment must have administrative knowledge. A Royal Army Medical Corps officer must have at the start of his duties a certain knowledge of administration. It was idle to say that ambulances had been lying idle week after week and month after month. If that were true he was glad, but there would be nothing to which the House would more readily condemn the War Office if at any given moment, when casualties were probable or possible, we had not the number of doctors at the front to deal with them.

Mr. Macpherson next came to the charge against the Army Council of refusing to utilize the services of persons because they were not registered practitioners. He would meet that first by a general claim which he could make without hesitation, namely, that nothing had been more wonderful in the course of this unparalleled war than the work done by the Royal Army Medical Corps. There

was no branch more open to criticism by the House of Commons, and the inefficient treatment of a gallant soldier was the one thing which would make any Government quit. The point he had to make was this: Ought they or ought they not, having a medical staff of the kind they had, to employ any man who was not upon the *Medical Register*? There were two bodies to be considered. The first was the Army Council itself. It had a responsibility to the private soldier. He could not choose his own doctor, and so long as he was a serving soldier, the army was responsible for his treatment. The State had said that any medical practitioner in this country who held himself out to be a medical practitioner must have passed certain statutory tests, and it stood to reason that any Government department must consider whether it would be right or wrong to ask any soldier to undergo treatment except by a medical man duly qualified by having passed those tests. That was a War Office responsibility. There was the other responsibility, which was purely technical and legal. He had nothing to say against the legal opinion of his learned friends, which was practically the same legal opinion which had been given by the law officers of the Crown. There was, so far as he could understand it, no objection to a private soldier going if he wished to have treatment from an unqualified man, but if he did so he must go on his own responsibility; the State could not be responsible. There was, however, the other and more difficult question, and he feared it would be putting an intolerable burden on Royal Army Medical Corps officers. The General Medical Council had the right to say that a man's name should be erased from the *Medical Register* if he employed an unqualified man. If the Army Council were to say that a medical practitioner duly qualified could send a soldier to an unqualified man, and he refused to obey, that being a medical command, the Army Council could dismiss him from the service. If, on the other hand, he did send the soldier to an unprofessional man, he might be obeying the Army Council instructions, but he would be disobeying the General Medical Council, and would have his name erased from the *Medical Register*. That would be putting the Royal Army Medical Corps practitioner in an intolerable position. He preferred, as far as he could, to meet the perfectly fair case that had been put forward. Mr. Macpherson continued: Whatever my private views may be, seeing that the officer is allowed to go there, and has gone whether allowed or not, and has, as my hon. friend said, been cured—some hon. member said that the misses were more numerous than the hits, and that is the point of the difference between us—I am prepared to say that I think the Army Council would not object if any private soldier wished and cared to take the risk and go to an unqualified practitioner if he thought that practitioner was going to do him any good, but he must take all these risks, for the War Office cannot do so. I do not think they could be asked in the public interest to make any further concession. That is as far as I would go; and the other difficulty, I must warn the House again, is, Who is to choose the unqualified practitioner? One man's name has been mentioned, but if you go to any town in Scotland the people there will swear by the local man and not by a man in London of whom they have never heard. All I can say is that I think the Army Council, in the case of the private soldier who cared to take the responsibility to go to an unqualified practitioner, would raise no objection.

The vote was afterwards agreed to.

Civilian Doctors in the Army.—Sir Garrod Thomas asked Mr. Macpherson, on August 8th, whether he was aware that, although the number of civilian doctors now in the Army Medical Service outnumbered members of the regular Royal Army Medical Corps by more than ten to one, the civilian doctors held none of the higher administrative posts which would give them power to introduce reforms or otherwise increase the efficiency of the Army Medical Service; and whether he would consider the desirability of taking action in this direction. Mr. Macpherson replied: At the present moment there are a large number of consultant medical men of the highest attainments employed both at home and abroad with the army, and these distinguished men are in constant touch with the

army medical authorities with a view to introducing reforms and increasing the efficiency of the Army Medical Service in such ways as experience may prove beneficial. Territorial and Reserve medical officers who have been granted commissions in the R.A.M.C. during the war hold a fair share of the administrative posts in the army. Throughout the war the line that has been invariably taken is that the best man should be employed where his abilities have the most scope, but it must be remembered that, however eminent a civilian medical man's medical attainments may be, he would be out of place in certain high administrative posts in the army through his want of knowledge of the administration and organization of the army as a whole. Where this experience has been gained through service during the present war, these officers are equally available with regular medical officers for selection to posts of responsibility. The whole subject has lately been under investigation by the committee presided over by Mr. Churchill. The report of this committee may be shortly expected.

Army Medical Advisory Board.—In reply to a question by Sir Garrod Thomas, on August 8th, as to the Medical Advisory Board of the Army Council, Mr. Macpherson said it had eleven members. Of these, seven were military and four were civilian doctors. The civilian members were paid £200 a year each for their services on the board; two military members received extra pay of £150 a year; five received nothing for this duty. The board held ten meetings in 1913, and seven in 1914. No formal meetings had been held since August, 1914, but all the paid members had been constantly consulted, and had given very valuable advice throughout the war.

Sir William Babbie's Position.—Asked by Major Davies whether the contents of the Vincent-Bingley Report of the Mesopotamia Expedition had been considered by the Army Council before the appointment of Sir William Babbie as Deputy Director-General of Army Medical Services, and if so, what reasons could be given for his selection to this post, Mr. Macpherson replied, on August 8th: Sir William Babbie was appointed Director of Medical Services (and not as stated in the question Deputy Director-General Medical Service) at the War Office on March 18th, 1916. The Vincent-Bingley report is dated "Simla, June 29th, 1916."

The New Education Bill.

The President of the Board of Education introduced his education bill in the House of Commons on August 10th. It proposes to give the Board of Education power to provide for the establishment of provincial associations after consultation with the authorities concerned, the local education authorities being empowered to delegate administrative and educational functions to these associations. County and county borough authorities will be required to submit comprehensive schemes of education for their respective areas larger than those of a county and county borough. The bill also proposes to require local education authorities to make adequate provision either by special classes or by central schools for what Mr. Fisher termed higher elementary education. He admitted the justice of the criticism that in much of the work the pupils of elementary schools do during the last two years they were marking time, and that their education was not fitting them for their future calling. The bill provided for the preparation of children for further education in schools other than elementary, and for the attendance of any child no longer under obligation to attend a public elementary school at a local continuation school for a period of 320 hours in a year, or an equivalent of eight hours a week. This would apply to every young person who had not received a full-time education up to the age of 16, and will continue to the age of 18. The schools would be provided by the local education authority, or by manufacturers in their works. Exceptions would be made in the case of young persons who had passed the matriculation examination of a university of the United Kingdom, or an equivalent examination, or shown to be unsuitable or deficient for part-time instruction. On the days of attendance at the continuation school or classes the young person must not be worked unduly long hours. The classes would be held

by day and not on Sunday or any holiday or half-holiday. There would be a considerable variety of type in these schools, those for the rural population being held mainly in the winter months. Care would be taken to secure a physical minimum in the schools for girls as well as boys, and to give to the instruction a vocational bias. The main features of the bill were summarized as follows:

1. To improve the administrative organization of education.
2. To secure that every boy and girl of elementary school life up to the age of 14 shall be unimpeded by the competing claims of industry.
3. To establish part-time day continuation schools, which every young person shall be compelled to attend, unless he or she is undergoing some suitable form of alternative instruction.
4. Proposals for the development of the higher forms of elementary education and for the improvement of the physical condition of the children under instruction.
5. The consolidation of the elementary school grants.
6. An effective survey of the whole educational provision of the country, all private educational institutions being brought into closer and more convenient relations to the national system.

The speech was received on the whole sympathetically by the House of Commons, but the attendance was very small. Mr. Fisher expressed the hope that the bill would be regarded as non-controversial, and seemed to entertain the expectation that it might be passed before Christmas. Further references to the scope and purpose of the bill are made at page 225.

The text of the bill, which was issued on August 14th, contains forty-seven clauses, including five extending the powers and duties of educational authorities.

Clause 17 gives power to supply or maintain, or aid the supply or maintenance of, holiday or school camps specially for young persons attending continuation schools, centres and equipment for physical training, playing fields, school baths and school swimming baths, and other facilities for social and physical training in the day or evening.

Clause 18 gives power to a local education authority to make provision for the medical inspection and treatment of children and young persons attending secondary schools provided by them; schools provided under the Welsh Intermediate Education Act, 1889; continuation schools under the direction and control of a local education authority; and such other schools or educational institutions, not being elementary schools, provided by them as the Board directs. It will also be authorized to exercise powers under the Education (Administrative Provisions) Act, 1907, in respect of children and young persons attending any school or educational institution, whether aided by the authority or not, if so requested by the management. The Local Education Authorities (Medical Treatment) Act, 1909, will apply where any medical treatment is given.

Clause 19 authorizes local educational authorities to supply or aid in supplying nursery schools and to attend to the health, nourishment, and physical welfare of children attending such schools.

Clause 20 empowers a local education authority in exceptional cases, such as residence far from a school, to provide board and lodging to enable children to receive the benefit of efficient elementary education.

Clause 21 authorizes the local education authority to aid teachers and students to carry on research in or in connexion with an educational institution.

Proposed Ministry of Health.—Mr. King asked the Prime Minister whether an assurance would be given that no bill would be introduced to establish a Ministry of Health until consultation had been had on the Government proposals with leading local government authorities, representatives of approved societies, and other bodies affected, and until at least an outline of the proposed changes had been made available to the public. Mr. Bonar Law, in a written answer, said that no bill would be introduced without full consultation with the parties interested.

Army Medical Re-examinations Committee.

Mr. Macpherson's Evidence.

At the sitting of the Army Medical Re-examinations Committee on August 9th Mr. Ian Macpherson, Under Secretary for War, gave evidence as to the authority for statements made by him in answer to questions in the House of Commons. The principal point was the assurance

he had offered on more than one occasion that no secret instructions had been issued with regard to the number of rejections of recruits. All his inquiries were addressed to a department of the War Office known as C2, which obtained details for him; he had to rely on that department. He had been assured that no instructions, oral or other, were issued except under Army Council instructions. Since the Committee began its sittings he had seen in print the confidential letter sent out by Sir Alfred Keogh. It was not based on an Army Council instruction, but was a confidential document sent out by General Keogh acting no doubt on some instruction. The Minister added that the facts upon which he based his replies in the House were invariably signed by the head of the department concerned. He did not agree that in this matter he had been misled. It all depended upon the view the military authorities took. They distinguished between a secret document and a confidential one. His own mind did not go to the niceties of these distinctions, but in military circles there was a big distinction. Asked what steps were taken to inform departments of any pledges given in the House of Commons, Mr. Macpherson said that Department C2 read through the Parliamentary Reports and cut out anything that was said by himself or any one else who was the spokesman for the War Office. It was then sent to the department concerned. He believed that all the pledges which he had given since he had been in office (since last December) had been embodied in Army Council instructions and kept. The instructions sent out to heads of departments were not looked upon by the military as secret instructions. A department had a right to send out any instructions it liked so long as they dealt with the work of the department. The witness was unable to throw further light upon the meaning the military attached to the terms "secret" and "confidential." He believed that an analogy existed between instructions sent out by a head of a War Office department and battalion orders.

Sir Alfred Keogh's Letter.

In reply to a question by Mr. Hogge as to the letter issued by the Director-General following on the Army Council instruction of September 7th, Mr. Macpherson stated that the letter was issued by Sir Alfred Keogh under proper superior authority. It was intended to deal with what, all those responsible agreed, was a real danger. Whether as the result of the issue of the Army Council instruction of September 7th or not, wholesale rejections, especially in certain parts of the country, were taking place of men who were useful to the army, though admittedly not up to the standard required in combatant units. It was therefore necessary to point out to the officials responsible for such rejections that the army service comprised a great variety of occupations answering roughly to those to be found in civil life, and that men capable of performing such service in the army must not be rejected. This was regarded as a perfectly legitimate corrective to administer to those by whom the mistake was being made, and it was quite properly addressed to them direct by their immediate official superior. The recipients of the letter had already had the Council instruction, and obviously the two were to be read together. The letter was marked "Confidential," and not secret, and if Mr. Hogge would read the rules in paragraphs 1857-1864 of the King's regulations dealing with the military distinctions between these terms he would realize that no official would have marked as "confidential" a letter intended by him to secure what appeared to be alleged by Mr. Hogge—the sinister purpose of securing by a subterfuge a modification of the declared policy of a superior authority.

In reply to a further question, Mr. Macpherson said he had already pointed out that the Army Council instruction of September 7th and the confidential document issued by a superior authority acting under proper instructions had to be read together.

The following members of the staff of the Dublin War Hospital have left for France: Lieut.-Colonel T. E. Gordon, F.R.C.S.I. (Adelaide Hospital), Major A. Blaney F.R.C.S.I. (Mater Misericordiae Hospital), Major Denis Kennedy, F.R.C.S.I. (Vincent's Hospital), Lieut.-Colonel T. G. Moorhead F.R.C.P.I. (City of Dublin Hospital), Major Preston Ball, M.D. (Hospital for Incurables), Captain R. J. Rowlette, F.R.C.P.I., pathologist (Jervis Street Hospital), Captain G. P. Meldon, M.D., anaesthetist (City of Dublin Hospital), Captain Corbett, M.D., oculist, Captain M. R. J. Hayes, F.R.C.S.I., radiographer (Mater Misericordiae Hospital).

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed in Action.

SURGEON S. N. TOULMIN, R.N.

Surgeon Stewart Newnham Toulmin, R.N., who was killed on August 2nd, was born in New York in 1892. He was the son of the late Mr. Joseph Toulmin, and received his medical education at the University of Edinburgh. After serving as a surgeon probationer on a destroyer for six months in the North Sea, he obtained leave to sit for his final examination, and took the Scottish triple qualification in 1915. He was shortly afterwards appointed a surgeon on H.M.S. *Endymion*. He then served with the fleet in the Mediterranean for about two years.

Died on Service.

FLEET SURGEON E. C. WARD, R.N.

Fleet Surgeon Edward Copley Ward, R.N., died in the Royal Naval Hospital, Chatham, on August 7th. He was educated at Queen's College, Cork, and at Edinburgh, and graduated as M.D. and M.Ch. of the Royal University of Ireland in 1883. He entered the navy soon after qualifying, and attained the rank of Fleet Surgeon on August, 21st, 1900.

ARMY.

Killed in Action.

MAJOR A. J. MARTINEAU, F.R.C.S.

Major Alfred John Martineau, F.R.C.S., Royal Garrison Artillery, was killed in action on April 17th. He was the youngest son of the late Judge Martineau, and was educated at St. Thomas's Hospital, taking the M.R.C.S. and L.R.C.P. Lond. in 1895, and also the F.R.C.S. Edin. in 1899. After filling the posts of house-surgeon at St. Thomas's Hospital, and at the Hospital for Sick Children, Great Ormond Street, and of house-physician to the Brompton Chest Hospital, he went into practice at Hove, Sussex, where he was surgeon to the Brighton Ear and Throat Hospital. He had served for many years in No. 1 (Brighton) Company of the Sussex Territorial Royal Garrison Artillery, and on August 26th, 1914, was promoted to the rank of major and to the command of the company. During the early part of the war he was stationed at Newhaven, in command of the fort at that port, and subsequently took his company overseas.

CAPTAIN W. R. ASPINALL, M.C., A.A.M.C.

Captain W. R. Aspinall, M.C., Australian Army Medical Corps, was reported killed, in the casualty list published on August 10th. He received the Military Cross just two months previously, on June 10th, 1917.

CAPTAIN G. D. EAST, R.A.M.C.

Captain Gordon Doulton East, R.A.M.C., attached Grenadier Guards, was killed in action on July 31st, aged 28. He was the only son of the late Mr. J. F. East, of Lewisham and Putney, and was educated at Cambridge, where he took a first class in the Natural Science Tripos in 1910, and graduated B.A., and at St. Bartholomew's Hospital. He took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1914. He was house-surgeon at St. Bartholomew's when he took a temporary commission in the R.A.M.C., and was promoted captain in October, 1916.

CAPTAIN A. C. EDWARDS, M.C., R.A.M.C.

Captain Alfred Cecil Edwards, M.C., R.A.M.C., was reported as killed in action, in the casualty list published on August 8th. He was the son of the late Canon Edwards, Vicar of Bingley, and was educated at Kirkby Lonsdale Grammar School, and at Liverpool University, where he graduated M.B. and Ch.B. in 1908, and, after acting as senior resident medical officer and honorary anaesthetist to the Northern Hospital, Liverpool, and as assistant surgeon to the Southern Dispensary, Liverpool, went into practice at Bingley, Yorkshire. He took a temporary commission as lieutenant in the R.A.M.C. on December 5th, 1914, was promoted to captain on completion of a year's service, and received the Military Cross on June 3rd, 1916.

CAPTAIN R. D. B. FREW, R.A.M.C. (T.F.).

Captain Robert Dunlop Black Frew, R.A.M.C. (T.F.), was killed in action on August 3rd, aged 32. He was the son of the late Colonel D. Frew, of Perth, and was educated at the University of Glasgow, where he graduated M.B. and Ch.B. in 1908, and M.D. in 1912; he took the D.P.H. of the Victoria University, Manchester, in 1914. After filling the posts of house-surgeon of Glasgow Royal Infirmary, of assistant medical officer of Monsall Fever Hospital, Manchester, and of resident medical officer of the Manchester Consumption Hospital, he became tuberculosis officer to the Borough of Wallasey Cheshire. He joined the 3rd West Lancashire Field Ambulance as lieutenant on May 14th, 1914, and was promoted to captain on completion of a year's mobilized service. He had previously been wounded in August, 1916.

CAPTAIN H. A. HARRIS, R.A.M.C.

Captain Hubert Alfred Harris, R.A.M.C., was killed in action on July 31st. He was the fourth son of the Rev. Frederick W. Harris of Putney, and was educated at Cambridge, where he graduated B.A., and at St. Bartholomew's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1910. He took a temporary commission as lieutenant in the R.A.M.C. on December 2nd, 1914, and was promoted to captain after a year's service. He had previously been wounded, and was attached to the Royal Field Artillery when killed.

CAPTAIN A. S. TAYLOR, R.A.M.C.

Captain Alfred Squire Taylor, R.A.M.C., was killed in action on July 31st, aged 28. He was the youngest son of the Rev. Dr. Taylor, ex-Moderator of the General Assembly of the Presbyterian Church of Ireland, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1914. At Edinburgh he was president of the University Union and captain of the University Rugby football fifteen. He was also a well-known Rugby International, having played three-quarter for Ireland in three contests. He took a temporary commission as lieutenant in the R.A.M.C. on October 12th, 1914, was promoted to captain after a year's service, and on January 11th, 1917, took a permanent commission in the R.A.M.C. as lieutenant and temporary captain. He was attached to the Highland Light Infantry, and was dressing a brother officer's wound in France when both were killed instantly by the bursting of a shell.

Died of Wounds.

CAPTAIN N. G. CHAVASSE, V.C., M.C., R.A.M.C. (T.F.).

Captain Noel Godfrey Chavasse, V.C., M.C., R.A.M.C. (T.F.), who has been reported as having died of wounds on August 4th, was the son of the Bishop of Liverpool. He was born on November 9th, 1894, and was educated at the universities of Liverpool and Oxford, graduating M.A., M.B., and B.Ch. at Oxford in 1912, and taking the diplomas of M.R.C.S. and L.R.C.P. Lond. in the same year. At Oxford he was a noted athlete, and represented his university against Cambridge in the sports in 1907 and 1908. In the former year he ran a dead heat with K. G. Macleod in the hundred yards, and was second to his twin brother Christopher in the quarter-mile. He had filled the post of house-physician and house-surgeon at the Liverpool Southern Hospital, took a commission as lieutenant and medical officer in the 10th (Scottish Territorial) Battalion of the King's Liverpool Regiment on June 2nd, 1913, and was promoted to captain after a year's embodied service. He received the Military Cross on January 19th, 1916, and the Victoria Cross on October 26th, 1916. The act for which he received the Cross was thus described.

For most conspicuous bravery and devotion to duty. During an attack he tended the wounded in the open all day under heavy fire, frequently in view of the enemy. During the ensuing night he searched for wounded on the ground in front of the enemy's lines for four hours. Next day he took one stretcher-bearer to the advanced trenches, and under heavy shell-fire carried an urgent case for 500 yards into safety, being wounded in the side by a shell splinter during the return journey. The same night he took up a party of twenty volunteers, rescued three wounded men from a shell hole 25 yards from the enemy's trenches, buried the bodies of two officers, and collected many identity discs, although fired on by bombs and machine guns.

Altogether he saved the lives of some twenty wounded men, besides the ordinary cases which passed through his hands. His courage and self-sacrifice were beyond praise.

His three brothers are all serving. His twin brother Christopher as a chaplain to the forces; his second brother, temporary Captain F. B. Chavasse, R.A.M.C., attached Liverpool Regiment, has been reported as wounded this week; and his youngest brother, Aidan, Second Lieutenant Liverpool Regiment, was recently reported as wounded and missing.

CAPTAIN R. W. SHEGOG.

Captain Richard Wellington Shegog, R.A.M.C., was reported as killed in action, in the casualty list published on August 13th. He was the elder son of the Rev. R. Shegog, late Rector of Skerries, and was educated at Trinity College, Dublin, where he graduated M.B., B.Ch., and B.A.O. in 1915, after which he took a temporary commission as lieutenant in the R.A.M.C., and was promoted to captain after a year's service. He had just completed two years' service.

LIEUTENANT J. SCOBIE, L.D.S.

Lieutenant James Scobie, L.D.S., Gordon Highlanders, died of wounds on August 3rd, aged 36. He took the diploma of L.D.S. of the Edinburgh Royal College of Surgeons in 1905, and was in practice at Hampstead till he joined the army in July, 1916.

Died on Service.

LIEUTENANT J. E. FOREMAN, R.A.M.C.

With reference to the death of Lieutenant J. E. Foreman, R.A.M.C., recorded in our issue of July 28th, we are informed that, after practising for a few years at Chiswick, he settled in Bournemouth and gave up an increasing practice to become R.M.O. at the Boscombe Military Hospital, where he won the high esteem of all with whom he came in contact. In spite of the sacrifice he had already made, and a previous rejection for military service on grounds of health, he felt impelled to apply for a commission, was accepted, and ordered to Egypt. While on his journey there the ship was torpedoed, and he had to spend the whole night in an open boat. Immediately after being rescued he developed scarlatina, then dysentery, and lastly enteric fever, of which he died. He was a gifted amateur musician, an excellent billiard player and cricketer, and an amateur mechanic of no mean order. He leaves a widow and three young children.

Wounded.

Captain W. B. Allen, V.C., R.A.M.C. (T.F.).
 Captain G. H. Barry, R.A.M.C. (temporary).
 Captain S. Brown, M.C., R.A.M.C. (temporary).
 Captain S. A. Bull, R.A.M.C. (temporary).
 Captain F. B. Chavasse, R.A.M.C. (temporary).
 Captain D. D. Craig, M.C., R.A.M.C. (temporary).
 Captain W. E. David, M.C., R.A.M.C. (temporary).
 Captain J. Dunbar, R.A.M.C. (temporary).
 Captain E. Evans, R.A.M.C. (temporary).
 Captain W. E. Fitzgerald, R.A.M.C. (T.F.).
 Captain F. S. Fletcher, R.A.M.C. (T.F.).
 Captain A. T. McCreddie, R.A.M.C. (temporary).
 Captain D. McVicker, R.A.M.C. (temporary).
 Captain H. R. Partridge, M.C., R.A.M.C. (T.F.).
 Captain G. A. Renwick, R.A.M.C. (temporary).
 Captain T. D. Renwick, R.A.M.C. (temporary).
 Captain G. C. Robinson, R.A.M.C. (T.F.).
 Captain H. Robinson, R.A.M.C. (temporary).
 Captain J. Ross, R.A.M.C. (temporary).
 Captain D. C. Scott, R.A.M.C. (S.R.).
 Captain C. W. Treherne, R.A.M.C. (S.R.).
 Captain J. Warwick, R.A.M.C. (temporary).
 Captain R. Young, R.A.M.C. (temporary).
 Lieutenant H. Deardon, R.A.M.C. (temporary).
 Lieutenant J. E. de Robillard, R.A.M.C. (temporary).
 Lieutenant G. L. Gell, R.A.M.C. (temporary).
 Lieutenant W. S. Kidd, R.A.M.C. (temporary).
 Lieutenant D. S. Pracy, R.A.M.C. (temporary).

Missing.

Lieutenant J. Rickards, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Chronnell, H., M.C., Captain Loyal North Lancashire Regiment, only son of Dr. Chronnell, of Hindley, Lancashire, killed July 31st. He was educated at Stonyhurst, where he was a sergeant in the O.T.C., and entered Manchester University as a medical student in 1913. He got his commission on October 5th, 1914, went to France in February, 1915, was mentioned in dispatches in November, 1915, got the Military Cross in

January, 1916, and served throughout last year's battle on the Somme.

Crerar, Ian Donald, Second Lieutenant Argyll and Sutherland Highlanders, elder son of Dr. Crerar, of 6, George Square, Greenock, killed July 31st.

Francis, Wilfrid Frederick, Second Lieutenant Hertfordshire Regiment, killed in action July 31st, aged 20. He was the third son of Dr. L. A. Francis, of Uxbridge, was educated at Berkhamsted, where he gained a scholarship at St. Mary's Hospital in October, 1914, but, after six months' hospital work, he joined the army, being gazetted second lieutenant Hertfordshire Regiment in April, 1915. He was wounded in France in July, 1916, but returned to the front in November last, and had not been in England since.

Green, C. L., Second Lieutenant 11th Essex Regiment, attached R.F.C., elder son of Dr. Edward F. S. Green of South Norwood. He passed his first examination in Edinburgh University, October, 1914, and joined the first Sportsmen's Battalion as a private, but obtained his commission in December, 1914. He was in the trenches in France from October, 1915, to August, 1916. He transferred to the Royal Flying Corps in September, 1916, and in January, 1917, he had a crash and broke his jaw, but rejoined in March and soon got his wings. He went to France on June 6th and was killed in action on June 9th.

Greenhill, Lieutenant C., M.C., killed in action on August 10th, eldest son of Dr. Robert Greenhill of Rutherglen. He was educated in the High School of Glasgow and joined up at the outbreak of war as private in the Lowland Division of Engineers (T.), and subsequently got a commission in the Royal Worcesters. He was awarded the Military Cross on June 3rd and promoted lieutenant after Messines.

Porritt, Thomas Handley, Second Lieutenant Coldstream Guards, died of wounds received in the last British offensive. He was the second son of Dr. William Porritt, Greytown, South Africa. Educated in South Africa, he had embarked upon a mercantile career, which he threw up, and, like so many colonials, came to the mother country at the call of patriotism and duty. He was given a commission in the Coldstream Guards, and had seen much service in France. He had been previously wounded, and had been awarded, but had not received, the Military Cross for exceptional bravery in leading his men in a raid into the German lines. His elder brother, who was wounded in the fighting in East Africa, is now in the Royal Flying Corps, whilst his father has joined the R.A.M.C.

Strain, John Loudon, Captain Royal Garrison Artillery, eldest son of Dr. W. Loudon Strain, of Wimbledon Hill, formerly of Sao Paulo, Brazil, killed August 1st, aged 20. He was educated at Kelvinside Academy, Glasgow, at Westminster, and at Trinity College, Cambridge, where he had passed the first M.B. He went to the front in September, 1916, and was promoted to captain in May, 1917.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SUPPLEMENT to the *London Gazette* issued on August 8th contains a further list of distinctions and promotions awarded in connexion with the war.

The following honours have been granted to medical officers for valuable services rendered in connexion with military operations in the field:

To be C.B.

Surgeon-Generals: John Chislett Culling, Richard Henry Quill, M.B. (retired pay).

Colonel (temporary Surgeon-General) Robert Samuel Findlay Henderson, M.B., K.H.P.

Colonels: Alfred Peterkin, M.B. (retired pay); Robert John Shaw Simpson, C.M.G., M.B. (retired pay).

To be K.C.M.G.

Colonel (temporary Surgeon-General) Michael Thomas Yarr, C.B., F.R.C.S.I.

To be C.M.G.

Lieut.-Colonels: Joseph Montagu Cotterill, M.B., F.R.C.S.; Harry Littlewood, F.R.C.S.; Bernard Ehrenfried Myers, M.D., N.Z.M.C.; George Speirs Alexander Ranking, M.D.; James Currie Robertson, C.I.E., M.B., I.M.S.; William Turner (retired).

Surgeon-Lieut.-Colonel and Hon. Surgeon-Colonel David Hepburn, M.D.

Temporary Lieut.-Colonels: Willie Netterville Barron, M.V.O.; William Lawrence Wright Marshall.

Majors (temporary Lieut.-Colonels): Hugh Thomas Dyke Acland, F.R.C.S., N.Z.M.C.; David Storer Wylie, M.B., F.R.C.S., N.Z.M.C.

The following officers of the home service have been promoted for valuable services rendered in connexion with the war:

To be Brevet Colonels.

Lieut.-Colonels: C. Averil, M.D.; H. L. Battersby (retired pay); J. P. Bush, C.M.G.; H. Charlesworth, C.M.G. (retired pay); C. P. Childe, F.R.C.S.; A. M. Connell, F.R.C.S.; H. E. Deane (retired pay); A. Dodd (retired pay); A. B. Gemmel; T. Gowans, M.B.; L. K. Harrison, M.B.; H. P. Hawkins, M.D.; T. H. Haydon, M.B.; A. G. Kay, M.B. (retired pay); J. R.

Kaye, M.B.; J. Marnoch, C.V.O., M.B.; F. Marsh, F.R.C.S.; W. J. Maurice, M.B.; R. R. H. Moore, M.D. (retired pay); D. V. O'Connell, M.D. (retired pay); S. P. Phillips, M.D.; J. A. Rooth, J. W. Smith, M.B., F.R.C.S.; C. J. W. Tatham (retired pay), H. J. Waring, M.B., F.R.C.S.; H. W. Webber, F.R.C.S.; F. H. Westmacott, F.R.C.S.; W. H. White, M.D.; G. S. Woodhead, M.D.

Brigade Surgeon Lieut.-Colonel J. F. Beattie, M.D. (retired list).

Lieut.-Colonel and Hon. Surgeon-Colonel A. Napier, M.D.

To be Brevet Lieut.-Colonels.

Majors (temporary Lieut.-Colonels): R. A. Bolam, M.D.; W. Butler, M.B.; A. B. Prowse, M.D., F.R.C.S.; C. Rundle, M.D.; J. Smart, M.B.

Major (acting Lieut.-Colonel) C. A. Lees.

Majors: T. D. Acland, M.D.; D. T. Belding, H. A. Berryman (retired pay), R. of O.; C. R. Browne, M.D.; A. Butler-Harris, M.B.; J. H. Drysdale, M.D.; C. H. Fagge, M.B., F.R.C.S.; T. A. M. Forde, T. Forrest, M.B.; C. E. P. Fowler, F.R.C.S. (retired pay), R. of O.; W. M. Gabriel, J. W. Gill, M.D.; H. W. Laing, M.D.; F. W. Lamballe, M.B.; A. P. Luff, M.D.; D. Renmet, M.D.; B. M. H. Rogers, M.D.; J. E. H. Sawyer, M.D.; H. Stott, D. Wallace, C.M.G., M.B., F.R.C.S.; G. W. Watson, M.D.; F. E. A. Webb, J. Wilson, M.B.

Surgeon-Major R. E. Lauder.

To be Brevet Majors.

Captains (temporary Lieut.-Colonels): E. H. Fenwick, F.R.C.S.; H. M. Rigby, M.B., F.R.C.S.

Captains (temporary Majors): W. C. Bosanquet, M.D.; D. W. Boswell, M.D.; E. S. Forde, R. L. Guthrie, M.D.; H. A. Leebody, M.B.

Captains: S. T. Beggs, M.B., R. of O.; J. A. Bennett, M.B.; C. R. Box, M.D., F.R.C.S.; R. C. Elmslie, F.R.C.S.; J. Ewing, J. Fawcett, M.D., F.R.C.S.; W. Guy, F.R.C.S.; H. P. Horne, M.D.; J. L. Joyce, F.R.C.S.; J. N. McLaughlin, M.D., S.R.; A. W. Ormond, F.R.C.S.; C. W. Rowntree, M.B., F.R.C.S.; A. Sellers, H. Sharpe, E. G. Smith, N. W. Stevens, M.B.; H. H. Taylor, F.R.C.S.; A. Walker, T. H. Ward, M.D.; W. J. Wilson, M.B.

To be Honorary Major.

Quartermaster and honorary Captain J. Wilson.

To be Honorary Captains.

Quartermasters and honorary Lieutenants: G. E. Barfield, E. C. Bennison, L. N. Blake, T. J. Spratley, J. C. Symonds.

All the above-mentioned officers belong to the A.M.S. or R.A.M.C. unless otherwise indicated.

Staff-Surgeon Gilbert Bodley Scott, R.N., has been appointed a Companion of the Distinguished Service Order in recognition of his services with the Royal Naval Armour Car Squadron in France, Russia, Turkey, and Rumania. The *Gazette* announcement records that on active service he has shown a devotion to duty and a forgetfulness of self which cannot be too highly praised.

The Emperor of Japan has conferred the order of the Rising Sun, second class, upon Surgeon-General George Welch, R.N.

NOTES.

MEMORIAL TO NAVAL OFFICERS.

ON August 1st, at the Royal Naval Barracks (St. George's Church), Chatham, three windows and a marble memorial tablet were dedicated to the memory of the officers and men of H.M.S. *Russell*, which was mined in the Mediterranean in April, 1916, and of H.M.S. *Swiftsure*, which lost thirty officers and men between 1913-16. Among the names of officers of H.M.S. *Russell* are those of two medical officers—W. R. Center, Fleet Surgeon R.N., and Philip D. Pickles, R.N.V.R.

England and Wales.

TUBERCULOSIS IN WALES.

THE Welsh National Memorial Association to the late King Edward, established mainly through the efforts of Major David Davies, M.P., has made another attempt to justify its title by securing the co-operation of the county of Pembroke, which hitherto has held aloof from the movement for the alleviation and eradication of tuberculosis in the Principality. At a meeting of the Pembrokeshire County Council at Haverfordwest the Public Health Committee reported that it was unable to recommend the council to join the association, and was of opinion that the time had now come to allow the Insurance Committee to make its own arrangements with the funds at its disposal. Mr. W. T. Davies moved the adoption of the report. Colonel Roberts, in seconding, said that the case of the county council was "that the only hope of eradicating the disease of tuberculosis lay in their retaining full powers of control. He was not willing to surrender the powers

vested in them by statute to an oligarchy at Cardiff" (the official head quarters of the Memorial Association).

An amendment referring the report back to the Committee was proposed by the Rev. Henry Evans and seconded by Sir Evan D. Jones, Bt., who characterized the report as the most hopeless confession of administrative bankruptcy that had ever been presented to any county council in the United Kingdom. He appealed to the council not to let pass the opportunity of dealing with an urgent necessity during the period of the war because of sundry fancied views of the "oligarchy at Cardiff." General Sir Ivor Philipps, M.P., on the other hand, asked the council not to surrender its powers to a private body like the Memorial Association; while another member said that the council was asked to join the association in the interests of "Home Rule for Wales." On a division, 10 voted for the amendment and 20 against. The Committee's report was adopted, and Pembrokeshire remains outside the National Memorial Association.

THE PROPOSED HEALTH MINISTRY.

A circular letter has been sent to Insurance Committees by the National Association of Insurance Committees conveying resolutions passed by the Executive Council of that Association with regard to the Ministry of Public Health. It appears that the Executive Council in June received a deputation from the standing committee of the National Conference of Industrial Assurance Approved Societies and the Joint Committee of Approved Societies, and after hearing their views, passed certain resolutions which in substance were as follows:

1. The Council urges the establishment of a Ministry of Health.
2. The Ministry of Health should be a separate department of the Government, and should co-ordinate all matters pertaining to the health of the nation.
3. The present scheme of National Health Insurance should be preserved.
4. A committee representative of all bodies now concerned with the administration of matters relating to public health should be appointed by the Government to inquire into and report to Parliament as to the powers and duties that shall vest in the proposed Ministry, and no bill be introduced until such report has been presented.

The Executive Council has also adopted a resolution received from the Derby and Derbyshire Insurance Committees expressing the opinion that it is eminently desirable that the machinery set up under the National Insurance Acts should be utilized to the fullest extent in any schemes relating to maternity and child welfare, and in any legislative proposals dealing with these matters. The circular letter asked for the support of Insurance Committees throughout the country. The Salford Insurance Committee has unanimously resolved to support the recommendations with the exception of the words "and no bill be introduced until such report has been presented." With regard to maternity and child welfare the Salford committee went a step further, and passed a resolution pressing on the Government the importance of hastening through the House of Commons a bill dealing with the matter during the present session, and sent copies of this resolution to the Prime Minister, the Chairman of the National Insurance Joint Committee, the President of the Local Government Board, to the members of parliament for Salford, and to all Insurance Committees. It was fully recognized that the state of public business in Parliament might prevent legislation this session, but every possible endeavour will be made to hasten legislation, especially in the matter of maternity and child welfare. The resolutions of the National Association of Insurance Committees represent a large and influential body of opinion which the medical profession cannot afford to neglect.

Scotland.

SIR WATSON CHEYNE, Bt., M.P.

SIR WATSON CHEYNE was elected on August 10th the parliamentary representative of the Universities of Edinburgh and St. Andrews without a contest. He was nominated by Professor Harvey Littlejohn, Dean of the Faculty of Medicine in the University of Edinburgh, and Dr. Barrie Dow, Dunfermline, Assessor of the University

of St. Andrews. Sir Watson Cheyne, in returning thanks, said that many problems had arisen, especially in connexion with education, which called for careful consideration. In regard to medicine, there was the problem of what to do with men who had given their all in the service of their country, for many had been ruined in doing patriotic work, and it would be necessary to do a great deal to set them on their feet again. The war had shown the great value of early scientific education, which was the main reason why the Germans had been able to make such a great fight. The organization of the universities as places where every sort of scientific training could be obtained required careful consideration, and in other directions—chemical research and commerce—much had to be done in the development of teaching facilities. He intended to go on with his surgical consultant work for the Royal Navy till the end of the war, but hoped to give up private practice in the near future and devote his energies to learning a new science—the business of politics.

Correspondence.

A NEW SCHOOL FOR THE STUDY OF HEART DISEASE.

SIR,—I think Dr. Poynton is not aware of what has been doing in this country for the prevention of heart disease and guidance of sufferers from heart disease. When in general practice I had twenty-five years ago in my private clinic carried on work specially to this end. When I joined the Mount Vernon Hospital in 1909 a clinic for this purpose was started. The opportunities there were not very great, but when I joined the staff of the London Hospital we started clinics specially devoted to this object. Before the war broke out there were half a dozen of us at work. We had started observations on all cases of rheumatic fever that came into the hospital and were watching the effect of enucleation of the tonsils on the rheumatic. We had another special department devoted entirely to ambulatory cases of heart affection where we watched the cases of damaged hearts and gave them suitable treatment to enable them to keep at their work, and studied the effects of remedies when thus employed. We also advised and helped others to get employment suited to their strength. This clinic was going strong and was being visited by physicians from all parts of the world when the outbreak of war interrupted our work.—I am, etc.,

London, W., Aug. 10th.

J. MACKENZIE.

ARMY MEDICAL ECONOMIES.

SIR,—Your correspondent "Train M.O." (July 28th, p. 135) seems to have been unfortunate in his experience.

Most divisions find additional work for their M.O.'s attached to divisional troops to fill in their—admitted—spare time, while at a time like the present he should, if in a battle area, be more than fully occupied assisting to cope with battle casualties at a dressing station.

With regard to their implied immunity from risk, I am at present sharing a tent with an engineer M.O. who has been decorated for gallantry in the field in the course of his ordinary duties.—I am, etc.,

August 3rd.

ANOTHER TRAIN M.O.

SIR,—A letter which appeared in your issue of July 28th by "Train M.O." contains such very inaccurate statements in regard to the duties of M.O.'s to R.E. units that I can only conclude it must have been based on very inadequate knowledge of the nature of their work. He states that "they never go near any fighting, and never do a full day's work." That is true of medical officers to divisional train, and divisional ammunition column, who are hardly ever exposed to enemy fire of any kind. The medical work of a divisional ammunition column can always be satisfactorily carried out in one hour a day. The R.E. medical officer is often the hardest worked in a division. He is usually billeted at divisional head quarters, where he is responsible for the health of never less than 500 troops, and often more. In addition he has three field companies, which sometimes are so scattered that it takes three to four hours or more on horseback to

complete their inspection, and this often under shell fire. Moreover, in an attack he is very frequently sent by the A.D.M.S. to the advanced dressing station of a field ambulance, or to a battalion to relieve a casualty M.O. Having acted as an R.E. medical officer for close on two years, and having met probably during that period not fewer than twenty M.O.'s of other divisional R.E.'s, I can affirm that it is the exception rather than the rule for them to be out of any big fight in which their division is engaged. It is only fair to these officers, several of whom have been wounded, that "Train M.O.'s" statements should be at once refuted.

On the question of economy I agree with him. The field ambulance of each brigade could look after these units quite well.—I am, etc.,

August 5th.

M.O., R.E.

RECRUITING MEDICAL BOARDS.

SIR,—With reference to your remarks on recruiting, in your issue of August 4th you state: "The mistake, it seems to us, has been that the presidents of these boards have been in so many instances retired regular medical officers unacquainted with civil conditions." I am at a loss to conceive what you mean by this statement. Surely the only duty of recruiting medical boards is to medically examine the men who come before them, and therefore "civil conditions" are a question for tribunals.

So far as my own experience on recruiting medical boards goes, all civil medical practitioners who have served on these boards have done their duty without "fear, favour, or affection," but it has been a most invidious task for a local medical man, in view of the fact that, with the exception of young lads just of age, practically every man who has been called up has been doing his best to avoid service. The task will become even more difficult when the civil medical practitioner can no longer shift the onus on to the shoulders of a military president who has been held by the War Office responsible for every classification.—I am, etc.,

August 7th.

W.

SIR,—It would be interesting to know how many ex-members of the R.A.M.C. were employed during the war, and what duties they performed. An opinion seems to prevail among the public that all medical boards on recruits for the army were presided over by members or ex-members of the R.A.M.C. or of the Indian Medical Service. That is not my experience. I live in a town of nearly four hundred thousand people, and during the war only one ex-army medical officer was employed in examining army recruits; and he did not preside at all the medical boards he attended. It should be clearly understood that, speaking generally, regular officers of the Royal Army Medical Corps of the executive branch did not perform duties at home during the war. All were engaged abroad. Therefore a distinction should be made between the regular officers of the R.A.M.C. and those civilian medical gentlemen who joined the army for the first time, with temporary rank to enable them to deal with soldiers. The medical examination of army recruits is not a simple matter. It requires sound professional knowledge, which our civilian medical brethren can furnish, but it also requires a thorough knowledge of the soldier and his duties under all conditions of service. This will be the most difficult condition with recruiting by civilians. It was stated in the House of Commons that recruiting in France is in the hands of civilians. It is forgotten that, except women and children, there are no civilians in France, where all men physically fit have been, or are now, serving in the army.—I am, etc.,

August 14th.

SURGEON-GENERAL (retired).

Universities and Colleges.

MEDICAL SCHOLARSHIPS.

THE following medical scholarships have been awarded by the London Intercollegiate Scholarships Board at the institutions indicated:

UNIVERSITY COLLEGE.—Bucknill Scholarship: A. J. Morland. *First Medical Exhibition: C. D. Shapland. *Second Medical Exhibition: V. Feldman.

* Subject to the confirmation of the College Committee.

KING'S COLLEGE.—Warneford Scholarships: M. Melgrave; P. M. Acheson and H. W. Snell, equal.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—Chemistry and Physics Scholarship: J. Pearce.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—St. Dunstan's Exhibition: E. V. Adams, Isabel Thorne Scholarship: D. N. L. Leverkus. Mabel Sharman-Crawford Scholarship: E. M. Store. Mrs. George M. Smith Scholarship: E. J. Williams.

UNIVERSITY OF LONDON.

ST. THOMAS'S HOSPITAL.—The following scholarships have been awarded:—Entrance Science (first £150, second £60): J. C. Churcher and N. S. Macpherson, being equal, divide the two scholarships. Arts (two, £15 15s. each): W. H. Dunn, E. G. Housden.

The Services.

EXCHANGES.

OCCULIST R.A.M.C., ophthalmic centre, France, wishes to exchange with officer holding similar appointment in United Kingdom.—Address, No. 2700, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

R.A.M.C. Exchange wanted. M.O. to a reserve park (horse transport) in France desires exchange with M.O. of a home service unit. Write for particulars to M.O., No. 2 Res. Park A.S.C., B.E.F.

Obituary.

ALEX. REID URQUHART, LL.D., M.D. ABERD.,

F.R.C.P. EDIN.,

FORMERLY PHYSICIAN SUPERINTENDENT OF THE JAMES MURRAY
ROYAL ASYLUM, PERTH.

WE regret to record the death, on July 31st, at Eastbourne, of Dr. A. R. Urquhart, for many years physician superintendent to the James Murray Royal Asylum, Perth. Dr. Urquhart, who was 65 years of age, graduated M.B., C.M. Aberd., with honours, in 1873, and M.D. in 1877; and in 1914 his university conferred on him the honorary degree of LL.D. He became F.R.C.P. Edin. in 1894. After graduating he held appointments as assistant medical officer at Dr. Newington's private mental hospital, at the Warwick and Berkshire County Asylums, and finally at the Perth County Asylum. He found his life work as physician superintendent of the James Murray Royal Asylum and Hospital for the Insane at Perth, an office to which he was appointed in 1880. When he retired in 1913 he was appointed consulting physician, and his many friends in Perth presented him with his portrait in oils by Mr. Fiddes Watt, A.R.S.A.

Dr. Urquhart for many years took great interest in the work of the British Medical Association, was honorary secretary of the Perthshire Branch, and for many years a member of the Parliamentary Bills Committee and of the central Council of the Association. He was secretary of the Section of Psychology at the annual meeting at Glasgow in 1888, its vice-president at Newcastle in 1893, and its president at Leicester in 1905. He was also a member of the special subcommittee of the Parliamentary Bills Committee on incipient insanity.

He was for some time joint editor of the *Journal of Mental Science*, and contributed to its columns a number of articles, especially on asylum organization, construction, and administration. He was the author of the article on asylum construction in *Tuke's Dictionary of Psychological Medicine*, on mental weakness in *Allbutt's System of Medicine*, and of numerous articles on insanity to the *Encyclopaedia Medica*. His eminence as an alienist was recognized in many ways; he delivered the Morison lectures on insanity before the Royal College of Physicians of Edinburgh in 1907, and was an honorary member of the Belgian, Italian, French, Canadian, and American associations and societies concerned with the speciality to which he devoted himself.

J. C. J. writes: Dr. Urquhart's reputation as an alienist and as an authority on all matters dealing with the treatment and control of the insane was world-wide, and no member of his speciality in this country was more closely in touch with the practice and views of those engaged in psychiatry on the Continent of Europe. He had travelled much and read much, and was a man of singularly broad and cultivated mind, keenly interested in art, literature, architecture, and all the refinements of life, but practical and business-like in all his conduct, and never satisfied if he was not taking a part in the affairs of his profession

and his community. For many years he acted as secretary to the Scottish Division of the Medico-Psychological Association, and had filled the presidential chair; a few days before his death he was elected an honorary member of the association, a distinction conferred on few.

Dr. CHARLES MERCIER writes:

How fast the old guard of alienists is disappearing! The ink is scarcely dry upon my tribute to Hayes Newington when I hear of the death of another old and dear friend, Urquhart, late of Murray's Royal Asylum at Perth. Dr. Urquhart was a physician of the highest type. Polished, urbane, well read, highly cultured, a master of his profession, learned in its history, and personally acquainted with the leaders of it, both in this country and abroad, he was the very model and exemplar of the highest class of physician. Of all my antagonists in controversy, Urquhart was the most satisfying. Humorous, witty, imperturbable in temper, deft in argument, and tenacious of his opinions, he was an ideal adversary, and as we never met without sparring, so we never parted without feeling that our friendship was increased. He gave me many a fall, but he always contrived that his antagonist should fall soft, and I found it impossible not to join in the laugh that he raised at my expense. It is not very long since he came to visit me, and to my great pleasure brought most of his family with him, and I saw little of the mental weakness of which he complained. It was certainly not apparent in his conversation, but he found himself unable to read, a great deprivation for so scholarly a man. He was a good speaker, and a better talker—but what was there that he undertook that he did not do well? May I, when my time comes, leave as fragrant a memory behind me!

MISS MARIAN WILSON, M.B., Ch.B. Edin., surgeon to the Scottish Women's Hospital (Hôpital Auxiliaire 301), Royaumont, France, died on August 1st, of acute appendicitis, at St. Martin-Vésudie, Alpes Maritimes, while taking a few weeks' rest with her relatives. Miss Wilson belonged to a Scottish family, and graduated in Edinburgh in 1906, but lived for some years in Lausanne, where she acquired a mastery of the French language. She had held the post of medical officer to York Dispensary, and subsequently spent several years in Palestine as a medical missionary in Jaffa and Hebron. On the outbreak of hostilities Miss Wilson returned to Lausanne, and joined the staff of Royaumont in November, 1915. Her surgical ability and conscientious work made her a most valuable member of the staff, and her distinguished services to the French wounded were recognized in February, 1917, when the French Government awarded her the Médaille des Epidémies en Vermeil. Miss Ivens, Médecin Chef of the hospital, Royaumont, writes of Miss Wilson that "her personal charm and extreme interest in and solicitude for her patients gained her their affection in an unusual degree, and after their return to the front they not infrequently walked many miles and spent many hours of their short leave in paying her a visit. In spite of a frail physique, with an admirable spirit Miss Wilson rose to the occasion during many periods of stress and fatigue. The news of her untimely death caused the deepest sorrow to her friends and comrades, in whose ranks her loss has created an irreparable gap."

LIEUT.-COLONEL COLIN WILLIAM MACRURY, Bombay Medical Service, retired, died in London on August 4th, aged 74. He was the son of the late Angus MacRury of Dunruadh, in the island of Benbecula, Outer Hebrides. He took the diplomas of L.R.C.S. and L.R.C.P. Edin. in 1866, that of F.R.C.S. Edin. in 1869, and the D.P.H. Camb. in 1883. He entered the I.M.S. as assistant surgeon on April 1st, 1869, became surgeon on July 1st, 1873, surgeon-major on April 1st, 1881, and brigade surgeon lieutenant-colonel on April 16th, 1893. He retired on March 31st, 1896. Most of his service was spent in the sanitary department of Bombay, where he was Deputy Sanitary Commissioner in various districts; in May, 1888, he was appointed Sanitary Commissioner, and held that post till he retired. He continued to take great interest in all questions affecting sanitation in India after his retirement, and in particular held strong views with regard to the measures which should be taken to check the prevalence of plague.

OUR BELGIAN COLLEAGUES AT HOME AND ABROAD.

At a meeting of the committee of the Belgian Doctors' and Pharmacists' Relief Fund, held on August 2nd at the offices of the *Lancet*, the accounts for the half-year ending June 30th, duly audited by Messrs. Crowdsen, Youatt, and Howard, chartered accountants, were submitted as follows:

Receipts.			Payments.		
	£	s. d.		£	s. d.
December 1st, 1916:			Relief	5,638	15 0
Balance	10,588	5 3	Clothes	37	3 1
June 30th, 1917:			Administration		
Donations	348	3 6	peuses	23	2 10
Interest	240	5 6		5,699	0 11
			Balance at bank, £2,511		
			13s. 11d.; Treasury		
			Bills at cost, £2,955		
			19s. 5d.	5,477	13 4
Total	£11,176	14 3	Total	£11,176	14 3

The Treasurer, Dr. Des Voeux, said that the receipts since the last meeting had been small, but no appeals had been made for some time. The expenditure on relief in England was also small now, but £800 a month had been sent to Belgium during May, June, and July. The committee decided to continue to send this mensuality, being assured of its safe receipt by those for whom it is intended. The Clothes Bureau is now at the St. Andrew's parish rooms, Palace Street, Westminster, and as the year goes on the need of clothes will again become acute.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand London; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand London; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Mediscra*, Westrand London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

S. desires to know whether there is any contraindication in the use simultaneously of potassium iodide and the appropriate vaccine in the treatment of actinomycosis.

INCOME TAX.

J. A. received about £500 as army pay in 1916-17 and lost about £200 on his practice during that year. The local surveyor of taxes declines to pool his earnings and assess him on the net total of £300, but proposes to treat his civil income as nil.

*. The War Office is responsible for the tax on the army pay and the pooling suggested is impracticable. But our correspondent is entitled to prefer a claim under the Customs and Inland Revenue Act of 1890 to be repaid on the amount of his loss through the conduct of his civil practice, which would lead to the same result. We therefore suggest that he write to the surveyor of taxes referring to the Act of 1890 and offering to supply any necessary particulars of his receipts and expenses for 1916.

REMOVAL OF MERCURY COATING ON RING.

H. has been consulted by a patient who, after using mercurial ointment on her child's head, finds a coating of quicksilver on her wedding ring. We are asked how it can be removed.

*. Thin films of mercury on the surface of any other metal disappear spontaneously in time owing to the fact that metallic mercury is slightly volatile even at ordinary temperature; the process, however, is very slow, usually requiring several months at least. If it is desired to

accelerate matters, by far the best method is to expose the article concerned for a short time to a temperature of about 400° C. and remove any mark or discoloration remaining by a little polishing; if, however, circumstances forbid resort to a high temperature, the following alternatives may be tried: (1) If the patches are not in contact with the skin, the cautious application of dilute nitric acid (concentrated nitric acid 1, water 2) will slowly remove the mercury; acid of this strength does not quickly stain the skin yellow, but is still strongly caustic and therefore too dangerous to be applied by the patient herself. (2) The only remaining practical method is to remove the adhering mercury, together with the surface of the gold, by mechanical abrasion with a powder such as precipitated silica, pumice, or very fine emery; if the film is only a thin one, this could probably be done fairly easily and without losing much of the gold, the surface being subsequently polished with jeweller's rouge.

LETTERS, NOTES, ETC.

THE ROWAN BERRY: A SIALOGOGUE.

H. DOWNES, M.B., F.L.S. (Ilminster), writes: Rowan berries contain a large amount of malic acid and a small quantity of hydrocyanic acid; probably the former is answerable for the sialogogue action. Malic acid is situated in the pericarp; its function is to prevent birds from eating the berries before they are quite ripe, or over-ripe, as we should consider it. As ripening proceeds the malic acid splits up the glucosides (probably assisted by a ferment), with the formation of sugar; the berries are then eagerly devoured by birds and the seeds thereby disseminated. An excellent substitute for currant jelly may be made from the berries.

A TOO-PUNGENT MOUTH-WASH.

MR. J. T. HALL (Bournemouth) writes: Dr. Goodrich asks on what I found my assertion that highly pungent washes, powders, and pastes are a source of marginal gingivitis. I reply, on clinical observation over a long period of years. The primary factor in the causation of pyorrhoea is, of course, dietetic; but there are contributory factors, and this is one. Perhaps the most flagrant example is to be found in the popular carbolic dentifrices, some of which are so pungent as almost to bring tears into one's eyes. Such powerful irritants cannot be used day after day without seriously affecting the oral tissues. Their discontinuance in favour of milder preparations has in many of my patients been speedily followed by marked improvement in the health of the mouth.

DEFORMED FEET IN WOMEN.

DR. WALTER KIDD writes: The present fashion of short skirts has afforded the opportunity of seeing that a very large proportion of women in our country have deformed and inefficient feet. This is almost entirely a matter of flat-foot, other deformities being trifling as to numbers. The subject was brought forward in *Nature*, May 10th, and in the *National Review* for July. It is not one which seems of immediate importance to the medical profession, for most of the sufferers are not affected enough to make them seek advice, and the present overburdened state of mind of most medical men makes them indisposed to look into a matter which can well wait till greater things are settled. But the fashion of short skirts, and its revelation as to women's faulty ankles and feet, may not be longer with us than other fashions have been. That the number of active young women with flat-foot, in one or both feet, is very large, no one with his eyes open can deny. Precise statistics may be useful; in any case the collection of them will have the effect of delaying or deferring *sine die* any general acknowledgement of the fact. But such statistics are not necessary. I have examined over a thousand persons, observing from behind as they walked, and am satisfied that not more than 10 per cent. of these had plumb-straight ankles, and that this is a generous allowance. A larger number might reveal 30 per cent. or 20 per cent., or perhaps only 5 per cent., but the deformity in question is so prevalent that it should be brought before the education authorities in order that foot drill may be enforced in all elementary schools.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0	5	0
Each additional line	0	0	8
A whole column	3	10	0
A page	10	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Observations

ON

TRENCH NEPHRITIS, ITS LATER STAGES
AND TREATMENT.

BY

J. MICHELL CLARKE, M.D., F.R.C.P.,

LIEUT.-COLONEL R.A.M.C.(T.).

SOUTHEAST SECTION, 2ND SOUTHERN GENERAL HOSPITAL;
PROFESSOR OF MEDICINE, UNIVERSITY OF BRISTOL.

THIS paper deals with cases of nephritis in a base hospital, the initial stage being over. All the patients came from France, except about six from Salonica, who showed no special features. The cases were taken in order of admission without selection. They were all under my immediate observation, and eighty cases seemed a sufficiently large number to represent the chief features of the disease.

The occurrence of nephritis on the large scale of the present war has afforded an opportunity of studying the first attack of the primary disease in young adults, which rarely occurs in civil hospitals, because in them the majority of cases of nephritis are exacerbations of a pre-existing disease. One would therefore be prepared for possible variations in the course and symptoms of the disease from those met with in civil practice, and possibly even for a new clinical type of nephritis, either as the result of the unprecedented physical conditions under which the men were placed and of a diet which mostly contained a relative excess of protein, or as the result of infection by a specific micro-organism. At the stage in which these cases were seen it seemed too late to make it worth while to carry out bacteriological investigations. The general result seems to point to a diffuse nephritis, chiefly affecting the convoluted tubules, focal in distribution in the kidney, and presenting a corresponding clinical syndrome with some special but no absolutely distinctive features.

In view of the youth of most of the patients, it might be expected that some cases classed as nephritis would in reality turn out to be examples of "functional albuminuria" or "albuminuria of adolescents," but this was not the case, and, speaking generally, this form of albuminuria has hardly been seen at this hospital throughout the war.

Taking the 80 cases admitted to the hospital with the label "nephritis," there were only 6 in which the diagnosis was at fault, and in which the patient was suffering from some disease with secondary albuminuria.

The remaining 74, for convenience of reference, are placed in four groups:

I. Thirteen cases in which there was either a distinct history of a previous attack of nephritis or definite signs of an affection of the kidneys of some standing.

II. Ten cases in which the nephritis was found to have cleared up on admission, though the symptoms of an attack before admission were quite definite.

III. Nineteen cases which completely recovered in hospital and were discharged cured.

IV. Thirty-two cases which left this hospital not cured, though the majority were greatly improved.

CAUSATION.

With regard to causation: In Group I, five, probably six, patients had had attacks of nephritis at some antecedent time, and one gave a family history of Bright's disease; four patients had had scarlet fever severely, two recently, one diphtheria followed by general anasarca, and four were either painters or plumbers before the war. In Group II, two had had scarlet fever, one recently, one trench fever shortly before, and one diphtheria three years before. In Group III, one had had scarlet fever, three bronchitis, and two malaria shortly before. In Group IV, three had scarlet fever in childhood, two diphtheria, four had recently suffered from malaria, but not severely, and in one the affection of the kidneys followed pneumonia eighteen months before. Twelve patients attributed the illness to standing in cold water, and four admitted alcoholism.

In three the illness began with a sharp attack of bronchitis, in two with pneumonia, in one with pleurisy and bronchitis, and in two with an attack of malaria.

There was no case in which the nephritis came on directly after being "gassed," and very few of the patients had been "gassed" at any time.

AGE.

The average age of the patients in Group I was 31.8 years; in II, 24.9; in III, 27; and in IV, 31.7 years. Those in Groups II and III, with early recovery, were thus decidedly younger than the others. Length of service appeared immaterial both to the incidence of disease and to its severity.

ONSET.

The onset in nearly all appears to have been sudden, and oedema of the face and limbs, with pains in the back, and dyspnoea the chief symptoms; the latter was only partly accounted for by the frequency of bronchitis. Oedema at onset was present in 57 out of 74 patients. Haematuria, generally slight, occurred in many.

LATER SYMPTOMS.

The chief symptoms of the disease whilst in hospital were oedema, most often of the face and limbs, much less often general anasarca; as a general rule oedema showed a disposition to clear up fairly quickly, but in bad cases was, of course, persistent, sometimes for many weeks, and in a few attended with ascites and pleural effusion; dyspnoea, often but not always associated with some bronchial or pulmonary complication; pains in the limbs and back, headache, less frequently vomiting, only occasionally diarrhoea, a feeling of great prostration, and sometimes mild cyanosis; anaemia was only present in the more severe cases and uraemic fits in one only.

Changes in the Cardio-Vascular Apparatus.

The changes in the cardio-vascular apparatus are summarized in the table. The greater frequency of all cardio-vascular changes in Group I, where there was evidence of past kidney trouble, is to be noted, also that the blood pressure affords a fair index of the severity of the case. The pulse pressure seems a little large in all, and especially in the severe cases.

Table showing Changes in Cardio-Vascular System.

	Hypertrophy of Left Ventricle.	Thickened Arteries.	Alteration in Heart Sounds.	Retinal Changes.	Average Blood Pressure in mm. Hg.		
					Systolic.	Diastolic.	Pulse Pressure.
Group I (13 cases) ...	5	5	11	5	147.9	90.8	57.1
Group II (10 cases) ...	0	0	5	0	123	76	47
Group III (19 cases) ...	0	0	9	2 (14)	131	83.7	47.3
Group IV (32 cases) ...	8	7	23	8 (29)	143	91.2	52
Total (74 cases) ...	13	12	48	15 (66)			

In most cases several observations on blood pressure were made. The highest systolic pressure taken was 193 mm. Hg, and the lowest diastolic 65 mm. Hg. The figures in brackets indicate the number of cases in which the particular symptom referred to was investigated. The blood pressure was taken in 10 cases in Group I; in 6 cases in Group II; in 13 cases in Group III; and in 23 cases in Group IV.

The blood pressure was estimated by the auscultatory method with French's sphygmomanometer, and the diastolic pressure was taken as the point of disappearance of the loud third sound. The changes in the heart sounds consisted of a ringing or accentuated aortic second sound, with occasionally a systolic murmur or reduplicated first sound at the apex, and except in Group I displacement of the apex-beat outwards, when present, was never great.

The retinal changes comprised two cases with intense retinitis, optic neuritis, numerous haemorrhages and yellow-spot changes—both died; one of mild optic neuritis, who also died; three of mild oedema of the optic disc; two of pallor or oedema around the disc, and five of decided thickening of retinal arteries (one "silver wire" in a painter at 41). No other instance of retinal haemorrhage was noted.

Urinary Changes.

The quantity of urine was generally small for some days after admission; in severe cases 10 to 20 oz. a day.

Later the quantity varied from 30 to 60 oz. a day, and was sometimes larger. Exceptionally the amount passed was small throughout, and some of these cases did quite well. Quite apart from treatment, there were periods of increased diuresis, as occurs in most forms of nephritis. An increased quantity of water did not always carry with it any considerable increase in the daily amount of urea.

The specific gravity of the urine was, generally speaking, low, the average being from 1015 to 1018, often below 1015, rarely over 1025, and fixation of specific gravity was seen in the more severe cases.

The quantity of albumin was often very large on admission, but in most soon diminished. In Group I on admission the average amount in 9 cases was 0.89 per cent., and in 3 a trace, and on discharge in 4 a trace, in the rest 0.26 per cent.; in Group IV the average quantity of albumin on admission in 22 cases was 0.46 per cent., in others a large to a small trace, and on discharge from 0.1 per cent. to a faint trace (Esbach's tubes).

Urinary casts were numerous on admission in most cases, except the mildest, and very abundant in the severe ones. They consisted generally of the epithelial, hyaline, and granular varieties, and fatty casts were rarely seen. In cases that recovered, the casts rapidly diminished, but were very persistent in small numbers. These statements apply to centrifugalized urine.

Decided haematuria in hospital was exceptional; in many cases the urine was smoky on admission and for a short time afterwards, and this condition was apt to recur occasionally; in still more the only evidence of blood was microscopic.

With regard to the nitrogenous excretion, in 4 cases in Group I, several estimations in each, the nitrogen excreted as urea was 53 per cent. of the total nitrogenous intake; and in 10 cases in Groups III and IV, several estimations in each, the average excretion was 67 per cent. of the intake. Urea was estimated by the hypobromite method, as more exact methods were not available. These cases may be taken as typical examples of varying degrees of severity.

As to excretion of NaCl, the amount in the food would vary from 4.5 to 6 grams a day; on the whole there was a deficiency in excretion of NaCl, but not to any great degree; it was most marked in severe cases and on admission, and improved as the case improved.

Thus in Group I the average excretion of NaCl was 4.9 grams a day (average of 5 cases with several estimations in each), whilst in a fatal case it was only 3 grams a day, and in Group IV the average excretion in 5 severe cases was nearly the same, 4.7 grams; and in 7 less severe cases it was 7.9 grams a day. In 3 of these it was at first as low as 1.5 to 2.2 grams.

Before estimations of urea and NaCl were made, the patients had been on a fixed diet of known quantity for some days. Three teaspoonfuls of salt were given in water to two cases of average severity and the excretion in the subsequent twenty-four hours was 10 and 12 grams respectively.

Phenol-sulpho-naphthalein tests were made on several occasions, and although in severe cases elimination was practically nil, unfortunately I can make no positive statement on this point, as the drug used was afterwards found by control tests to have deteriorated.

DURATION OF ILLNESS.

The average duration before admission to this hospital was two to three weeks, and that of the whole illness until the cases were sufficiently recovered for discharge was, in Group I, 9.6 weeks, in Group II (convalescent on admission) three weeks, in Group III (recovered in hospital) 6.8 weeks, and in Group IV, 8.1 weeks.

RESULTS.

The results were far worst in Group I; of these 13 cases, 1 died, 5 were discharged *in statu quo*, 5 showed some improvement, and in 2 only had the albumin and casts disappeared, and they might be considered well. Groups II and III are composed of cured cases. Of 30 cases in Group IV, 2 died, 3 were discharged not improved, 5 with casts and a considerable amount of albumin in the urine, and 12 with only a faint trace of albumin, or on some days none, and with a few casts present at intervals. The last 17 patients were sent to auxiliary hospitals and subse-

quent inquiry has elicited that 5 have fully recovered, 6 are much better and doing light work, and 2 unchanged.

To sum up: Of 68 patients, 3 died, 8 were discharged slightly improved as permanently unfit, 11 much improved but the urine contained casts and more than a trace of albumin, 6 fairly well and able to do light work, and 32 recovered completely; of 8 patients I have not sufficient information. It has already been pointed out that the younger patients gave the highest proportion of recoveries. It may also be noted that the only two cases in which there was intense retinitis and the only one with distinct optic neuritis died.

Ultimate Prognosis.

I think that in those cases who left the hospital with urine free from albumin and casts, with a kidney functioning well, with a normal blood pressure and without signs of any cardio-vascular impairment, it is reasonable to expect a permanent cure, provided they are not placed under too unfavourable conditions. Probably the same may be said for those in whom the above conditions obtained, with the exception of a faint trace of albumin, and results of inquiry as to the subsequent condition of several of them support this view. If, as is probable, the nephritis is of focal distribution in the kidneys, persistence of a trace of albumin and a few casts in the urine may be attributed to the slow healing of a focal patch, the rest of the kidney being unimpaired, and the condition may be expected to clear up in time, though for this it is obviously essential that the patient should lead a careful life.

If there have been previous attacks of nephritis or evidence of pre-existing (to the attack) cardio-vascular-renal changes, then it is unlikely that the patient will completely recover.

With regard to cases in which, after a first attack, moderate or considerable albuminuria remains after three months, or there is evidence of cardio-vascular changes, further lapse of time is required to show the result, but the prognosis may be regarded as unfavourable, especially in men over thirty-five years of age.

TREATMENT.

Rest in bed was insisted upon at first, and in all cases until either the albuminuria and casts had cleared up and there was a fair balance between the intake of nitrogenous foods and salt and the output by the kidney, or until it seemed that there was no prospect of the albumin and casts disappearing. The presence of blood in the urine was a further reason for complete rest, and also for great caution in increasing the amount of food, especially as to the addition of egg-yolk, fish, and chicken to the diet.

Diet.

Severe cases were placed on milk only on admission. The large majority were on a fixed diet of milk 2½ pints, bread 6 oz., rice 1 oz., butter ½ oz., potatoes 4 oz., greens 4 oz., jam 1 oz., and fruit occasionally. As improvement took place the bread was increased to 8 oz. and the yolk of one or two eggs was added. Later on, 4 oz. of cooked fish or chicken were added and sometimes more bread and butter. Salt was not used as a condiment, nor added by the cook, except in cooking green vegetables. The amount of water was not restricted when once the kidney began to secrete freely. It is essential to know the amount of food by weight that a patient with nephritis is taking, and reliance cannot be placed on the ordinary hospital dietary unchecked, as the amount taken by individual patients varies greatly.

Drugs.

Many of the patients had only a simple diaphoretic mixture with a saline or other purgative when required. Hot-air baths were used when free diaphoresis was necessary. Nitroglycerin was given when the blood pressure was raised. Iron was given in the later stages if there was anaemia.

In many cases with deficient urinary excretion on admission, the treatment with sodium carbonate, suggested by Dr. Martin H. Fischer, was used with very satisfactory results in establishing a free flow of urine. Dr. Fischer attributes nephritis to an abnormal production and accumulation of acid in the kidneys, and the oedema, anasarca,

and other symptoms of nephritis to a similar process occurring in the tissues, and the object of his treatment is to diminish the concentration of acid by giving water freely and to neutralize it by an alkali. This may be given by mouth, or if not absorbed thus, by rectal or intravenous injection. The treatment is not suitable for chronic interstitial nephritis, which has a different origin.

alkaline treatment with digitalis and caffeine is efficient when they fail singly as diuretics.

Although the excretion of urea was also increased to a varying extent in different cases—for instance, in the foregoing case, on one day with 90 oz. urine, specific gravity 1010, urea excreted was 28.5 grams, or N 12.38 grams (with intake of N about 10 grams), albumin 12.75 grams

CHART 1.—Illustrating the rapid and free diuresis produced by administration of sodium carbonate (see also Chart 2). A—A, Sod. carb. gr. xv hourly; bowels moved once daily. B, Trinitrin $\frac{m}{j}$ of 1 per cent. solution four-hourly.

CHART 2.—From the 24th to the 29th day of illness sod. carb. gr. xij was administered every hour, and from the 29th to the 35th day every three hours. Bowels moved twice daily.

CHART 3.—Shows a slower effect of sodium carbonate. A—A, Adrenalin, 1 in 1,000. mij t.i.d. B—B, Sod. carb. gr. xv hourly; bowels moved once daily. C—C, Tr. digitalis mxx twice daily. Patient had had scarlet fever twelve months before.

Whatever view be taken of this explanation of the pathology of nephritis, there is no doubt that the treatment is often most efficient in producing free diuresis in about forty-eight to seventy-two hours with disappearance of oedema and relief of accompanying symptoms, such as dyspnoea, headache, etc.

Pure crystallized sodium carbonate ($Na_2CO_3 \cdot 10 H_2O$) was given in doses of gr. x–xv in 8 oz. of water every hour during the daytime; the interval was increased to two to three hours after free diuresis had lasted two to three days. In two cases where administration per os was not feasible the rectal injections advised by Fischer (sod. carb. 10 grams, sod. chlor. 14 grams, water to 1 litre) were given every six to eight hours, but without success.

Most patients took this large quantity of fluid well, without special discomfort; two or three objected to it, and in three cases it had to be stopped because of nausea or vomiting. No other outward effects were observed. Reference can only be made to a few cases typical of many treated in this way. Charts 1 and 2 illustrate the rapid and free diuresis produced. Chart 3 shows a slower effect, the urinary excretion

rising gradually with some fluctuation during four to five days and then maintaining a level of 80 to 110 oz. for eighteen days. The diuresis was followed by disappearance of oedema and amelioration of symptoms.

Chart 4 illustrates a very severe case in a patient, aged 20, with uraemic symptoms and extreme general anasarca. The effect of the alkaline treatment was remarkable; as the chart shows, in ten days the anasarca had disappeared, and from an apparently hopeless case he had become convalescent. In this case and in one or two others it has seemed to me that the combination of the

NaCl 28 grams—the chief effect was on the excretion of water and salts.

In a few cases the treatment failed for no ascertained reason.

In one case uraemic fits, the only instance in the whole series of cases, occurred on the sixth day of treatment, but they did not recur; free diuresis set in next day, dropsy disappeared gradually, and he made a good recovery.

Adrenalin.

One other point in treatment may be mentioned.

Several patients complained of feelings of great prostration, attended with a low blood pressure. Relief was given by the administration of adrenalin chloride (1 in 1,000) mij every four hours.

PATHOLOGY.

With regard to the pathology I have little to say. Of the three fatal cases, a *post mortem* was allowed in one only. This was a patient in Group IV, of 23 years of age, with no history of previous illness except bronchitis as a child. He had never had scarlet fever, nor been "gassed." He was admitted with oedema of the face and legs and general bronchitis, with coarse, moist râles over both lungs, slight enlargement of the left ventricle of the heart, and a systolic apex murmur. The systolic blood pressure was 198 mm. Hg, and the diastolic 140. Liver and spleen not enlarged. He had double optic neuritis and intense retinitis, with numerous haemorrhages. The urine was scanty, specific gravity 1013 to 1016, contained a large quantity of albumin, no blood, and abundant hyaline, epithelial, granular, and fatty casts. He died of diffuse bronchopneumonia, with some haemoptysis. The sputum contained pneumococci.

CHART 4.—A very severe case of trench nephritis. A—A, Sod. carb. gr. vij hourly. xxx Saline enemata every six to eight hours on these days. B—B, Tr. digitalis mxx every six hours. C—C, Sod. carb. gr. xij hourly from the ninetieth to the ninety-fifth day, every two hours for the remainder. D—D, Tr. digitalis mxx , caffeine gr. v. every six to eight hours; twice daily after the 103rd day of illness; anasarca and dropsy disappeared.

with coarse, moist râles over both lungs, slight enlargement of the left ventricle of the heart, and a systolic apex murmur. The systolic blood pressure was 198 mm. Hg, and the diastolic 140. Liver and spleen not enlarged. He had double optic neuritis and intense retinitis, with numerous haemorrhages. The urine was scanty, specific gravity 1013 to 1016, contained a large quantity of albumin, no blood, and abundant hyaline, epithelial, granular, and fatty casts. He died of diffuse bronchopneumonia, with some haemoptysis. The sputum contained pneumococci.

The following is the report of the condition of the kidney:

This shows a condition of focal nephritis with evidence of several acute attacks recent in date.

Capsule thickened in patches. Blood vessels do not show arterio-sclerotic changes. Glomeruli normal in places; in others they show capsular fibrosis and fibrosis or atrophy of glomeruli; elsewhere there are intracapsular exudation, cell proliferation, and fibrosis. The interstitial tissue is increased in patches, and contains many areas of lymphatic spaces laden with fat.

The convoluted tubules are almost normal here and there, but to a great extent show cellular degeneration, especially fatty desquamation and degradation of the lining cells and granular debris in the lumen. Some show dilatation, and a few cystic spaces are present in the subcortical area.

The heart shows interstitial myocarditis in some areas.

The spleen, suprarenal, and pancreas are normal.

So far as this case goes it would confirm the clinical evidence, which points to this form of nephritis as being a diffuse nephritis, affecting chiefly the convoluted tubules, but not especially the vascular elements of the kidneys. The characters of the urine, with its rather low specific gravity, excretion scanty at first and later as a rule abundant, moderate or large amount of albumin, and with numerous hyaline, epithelial and granular casts in the early stages, correspond to a change of this kind.

To sum up, in cases of nephritis at a base hospital, the general clinical features perhaps especially characteristic are the benign character of the nephritis in the large majority, the frequency of pulmonary complications, especially bronchitis, oedema of lungs, and broncho-pneumonia, apart from these complications a not infrequent dyspnoea, the generally good appetite, clean tongue, and maintenance of fair nutrition, and, on the other hand, infrequency of anaemia, of marked uraemic symptoms, and of a high blood pressure or cardio-vascular changes. The short duration of the illness in most cases would explain some of these latter departures from the usual symptoms of other types of nephritis. Severe retinitis or optic neuritis is uncommon—3 out of 80 cases.

I regret that more thorough investigations on the blood and on the excretion of uric acid, creatinin, etc., could not be carried out, and in conclusion it is my pleasing duty to thank the resident medical officers at Southmead Hospital, especially Captain H. H. Carleton, R.A.M.C., for much help in taking blood pressures and other investigations, and Professor Walker Hall, of the University of Bristol, for pathological reports, and to express our great indebtedness to the Medical Research Committee for their help in maintaining the pathological laboratory at Southmead Hospital, in which the urinary examinations were carried out.

REAMPUTATION.

BY

W. A. CHAPPLE, M.D., Ch.B., M.R.C.S., D.P.H.,

MAJOR R.A.M.C.

OPERATING SURGEON, PAVILION MILITARY HOSPITAL
FOR LIMBLESS MEN.

ASSEMBLING that a reamputation of a limb has to be done, at what period after the primary amputation should it be undertaken?

The practice of surgeons differs widely. Some wait for healing and a "clean" operation which often takes months. But an experience of the use of button-sutures threaded through vulcanite boat-shaped buttons or india-rubber tubing acting as a support for the flaps and taking all the tension off the skin stitches shows that it is possible to reamputate in the presence of suppurating surfaces with almost complete certainty of union either by first intention or a kind of second intention, with preservation of the apposition of the flaps and the covering of the end of the bone.

Men upon whom an urgent amputation has been done in France arrive at hospitals in Britain after an interval varying from several days to a week or two.

If the amputation has been of the guillotine variety, the incision in the skin has been clean and circular, the skin is retracted up the limb, the muscle surfaces have retracted to a lesser degree, the end of the bone is exposed and protruding, and all the surfaces are bathed in pus.

Sometimes flaps have been attempted and a similar

condition exists, with the addition that the flaps may be large, hanging, and ragged at the edges from stitches which have cut through owing to suppuration.

My own invariable practice ever since the commencement of the war has been to allow these cases to settle down in hospital for a few days and then to reamputate, stitching the skin edges together as for a clean operation. During the waiting days the exposed surfaces are dressed with moist antiseptics, and when the general condition (usually disturbed by the journey and the necessary handling) has improved, the resistance has reached its maximum and the temperature has become steady, though slightly elevated, the patient is considered ready for operation.

When there was nothing other than the condition of the stump to consider reamputation has, as a rule, been done within a week or ten days of the patient coming in.

In no case have the skin and soft tissues failed to heal over the end of the bone by either first or second intention, with at worst, and rarely, a small granulation area at the point where the drainage tube was left in for the first twenty-four or forty-eight hours; or where some pus had formed at a skin stitch or between two stitches. Even when this pus has formed it has not interfered with the complete healing of the soft tissues over the end of the bone and the union of the skin, usually within twenty-one days. In no case has the end of the bone appeared or been exposed even to the probe after a reamputation. That this is not the general rule there is abundant evidence at the Pavilion Military Hospital for Limbless Men. It would appear that reamputations have been done and the bone shortened, but that the condition of the stump has reverted to its original state, the skin and other soft tissues retracted, and the bone exposed, the only difference being that the limb is shorter.

The secret of healing by primary or by secondary, or rather delayed primary, union in septic cases is the relief given to the skin stitches by the "button-sutures" planted well back from the incision, and arranged staple-wise in such a way and position as to bear the whole weight of the flaps and keep them in apposition.

The "second intention" to which I have referred is a union in the presence of or following suppuration affecting the skin edges, but not sufficient to separate those edges from each other (either by the stitches cutting through or by sloughing) to such a distance as to prevent the epithelial margins from uniting without the intervention of a granulation area.

As the button sutures carry all the weight of the flaps and bear all the tension, the skin stitches have no other function than to keep the skin edges opposite one another and prevent bulging of subcutaneous tissues. In short stumps the loss of another inch of bone by reamputation may seriously curtail locomotion. With button-sutures less provision has to be made for long flaps to meet contraction, and therefore valuable length is saved. These button-sutures tend also to keep the severed tendinous ends and muscle edges in apposition over the end of the bone. This either gives attachment between the two groups of locomotor muscles over, or it gives attachment to, the end of the bone. If it unites by close fibrous intervention over the end of the bone the result is a greater muscle purchase, and therefore a greater power of movement of the stump than would follow an attachment higher up the shaft, which is usual when muscles are allowed to retract after amputation. Moreover, a muscle shortened by contraction and attachment higher up suffers the disadvantage in "pull" that a rower does at the end of his stroke, as compared with the advantage at the commencement, when his arms are fully stretched and the point of "attachment" to the oars most distant from the base to which they have to be drawn. It should never be forgotten that a stump is a locomotive organ as well as a weight-carrying organ, and will have to swing and control an artificial limb often as heavy as 7 lb. It is also of advantage to get a substantial boss of soft tissue over the end of the bone. Even if atrophy takes place under muscle pull or from the pressure on an end-bearing stump the residuum is something to the good. In my opinion an effort should always be made to get a stump that will stand the pressure of the body weight. Even if this may not be urgently required, as in a short thigh stump, it has certainly two advantages—it shares the body weight with the tuber ischii, and, from the sense of firmness and

compactness it gives the man, he has a better control over his artificial limb.

The normal heel is the ideal stump. It is dome-shaped; it is covered with true skin, which thickens and hardens with use; it has a boss of fat, honey-combed with connective tissue, and it has a dome-shaped bone-end covered with periosteum. Every amputation should aim at giving a stump having these characters.

As a typical case of reamputation through the thigh, take an emergency operation done in France through the knee-joint. The condyles of the femur are exposed, the cartilaginous surfaces are ulcerating off, and the bone is carious when the case comes to Britain.

Four weeks have elapsed since the first amputation. A long anterior and a short posterior flap are dissected up in the lower third of the femur, sufficient of the muscular tissues being included in the flaps (but at a slightly higher level) to cover the end of the bone completely and easily with muscle. A circular incision is made through the periosteum well to the distal side of the point in the femur where it is to be severed with the saw, and a cuff of periosteum turned back little by little with the aid of a periosteal elevator, care being taken not to split or tatter or buttonhole this periosteal cuff. If the periosteum is rolled back one-eighth of an inch at a time, it will not split into ribbons, a defect in technique that tends to favour the formation of spurs. These spurs in many cases appear to be the result of grafts arising from osteoblastic cells from the sawdust distributed along the line of the saw edge. To prevent this I follow the plan of having the muscle and soft tissues well covered and retracted by a cotton-cloth retractor during the sawing and then washing the bone dust away thoroughly with 1 in 1,000 perchloride solution before the retractor is removed. Any muscle tissue that has been torn with the saw should be snipped away.

After the bone has been sawn through and the sharp edges rounded by a file or cutting forceps, and the vessels picked up with artery forceps, the nerves are found and cut back. I have followed the practice of making a circular incision through the sheath of the larger nerves, and then with a dry gauze swab rolling up the sheath beyond the point at which it is intended to sever the nerve. This allows the nerve end to be covered with its sheath in a manner somewhat similar to the periosteal covering provided for the end of the bone.

After all vessels have been tied, a purse-string catgut suture is stitched round the free edges of the periosteum, and then tied in such a way as to cover the end of the bone completely. If suppuration take place beyond this, the bone is protected.

The next step is to put in the "button-sutures." If boat shaped vulcanite buttons are not available, rubber tubing can be used and button-sutures prepared by the theatre sister. These consist of two silkworm-gut sutures knotted through a piece of rubber drainage tube 1 in. to 1½ in. in length and the size of a slate pencil, or through the vulcanite boat shaped buttons.

If rubber tubing is used, the silkworm-gut threaded on a needle is passed through the substance of the tube near its cut end, and then along the lumen of the tube to about the centre of its length. The needle is then made to pierce the tube and emerge on its outside. The other silkworm-gut suture follows a similar route from the other end of the tube, and then the two ends are knotted with a reef knot on the outside of the tube at its centre.

This double silkworm-gut suture thus prepared is now inserted in the lower flap about 1 in. or 1½ in. from the skin edge, staple fashion, with the tube parallel to the line of incision, and the ends are then carried through the anterior flap about 2 in. or 2½ in. from the skin incision. The ends are then threaded through a piece of tubing (b) similar in length and size to its mate (a), but having an eye cut out of its middle by the scissors, through which the ends of the silkworm-gut are made to emerge from the lumen of the tube after having been passed through either end.

The ends are then knotted after the flaps have been compressed well in apposition, and the skin edges are then sutured in the ordinary way, a small drainage tube being

placed in one angle of the wound. The whole wound and the buttons are then sprayed with iodine, and the stump bound upon a Gooch splint.

These button-sutures keep the flaps in apposition and prevent sagging. They also prevent oozing of blood between the flaps and the formation of a miniature haematoma. They thus tend to prevent haemorrhage by the pressure which the flap surfaces are made to exert against each other. But their great virtue is that they defy the results of suppuration. The skin underneath the buttons may, and sometimes does, ulcerate at the point of passage into the skin of the silkworm-gut, but in my experience the skin has rarely given way or failed to support the pressure of the buttons in such a manner as to allow the flaps to part. The skin has thus no tension to bear and the edges readily unite. Tension, and not pus, is the enemy of union.

If profuse suppuration occur, and pus oozes between and around the skin stitches, they can still be left *in situ*, and small tubes may be inserted here and there between them. These skin sutures may even in the course of eight or ten days cut through, but as there is no tension to speak of tending to part the edges, they do not part. All the time the button-sutures, being some distance back beyond the troubled edges of skin, are free from pus and carry the whole weight of the heavy flaps and counteract contraction. The channels of these button-sutures may even suppurate and pus may well up along one or more of the strands of silkworm-gut. But they do not give way and the healing and restoring processes are going on all the time, till, in from ten to fourteen days, the wounds are either quite healed or sufficiently healed to do without the aid of the skin sutures, and finally in a few days later the button-sutures also.

The importance of this method of dealing with stumps lies in this, that the reamputation can take place at almost any time after the primary operation, notwithstanding that the stump is septic, with the practically certain assurance that the flaps will not part nor the end of the bone uncover.

The following are individual cases illustrating these points:

CASE I.

Pte. D., wounded August 6th, 1916. Thigh amputated in lowest third three days later (August 9th). He arrived in England twelve days later (August 21st). The stump had been covered by anterior and posterior flaps, but the whole had suppurated, the stitches had cut through, the flaps had separated, were bathed in pus, had sloughing edges in parts, and were hanging free. The bone, denuded of periosteum, was protruding about 1½ in. It was seventeen days later before the sloughs had separated and the flaps were brought to a condition of normal cleanliness for granulating surfaces. One of the flaps had several "fingers" made in the margin by the original stitches having cut through.

On the seventeenth day after his arrival in hospital here, the stump was reamputated. The bone was removed at a point beyond the ring of callus and high enough to give a periosteal cuff; the "fingers" were trimmed off, the flaps slightly extended upwards by incisions at their base, and the whole stitched up and completed as if it were a "clean" operation. Button-sutures were put in, the skin edges were closely stitched, and two small drainage tubes were put in at either angle of the wound.

In this case the granulating surfaces of the flaps were brought in apposition by the button-sutures, but in some parts granulating surface came in apposition to a clean cut surface. Sero-pus discharged from the tubes and they were kept in for five days. Pus appeared at three other points in the incision. No skin stitch completely cut through, and on the tenth day several of the looser ones were removed. Between most of the skin stitches the edges had united by first intention.

Small quantities of pus oozed from some parts of the edges and the stitch channels for several days longer, but by the twelfth day all the skin stitches were out and all the edges were united either by first intention or by second intention, except at three points—the two drainage tube openings and one small point in the centre where the edges were sufficiently parted to allow of granulations to appear. The button sutures were removed on the twelfth day. In three weeks the whole had healed.

CASE II.

Pte. B. was wounded in France on June 25th, 1916; was amputated through the middle of the thigh four days later, and arrived in hospital in England on August 21st about eight weeks after his first amputation. The skin and soft tissues had retracted and about one inch of bone protruded. On August 26th—that is, five days after his arrival—he was reamputated. The incisions necessary to prepare anterior and posterior flaps of equal length were made at the edge of the skin just before it merged into the epithelial margin, so that skin to skin was brought into apposition by the skin sutures. The rest of the operation was similar to Case I and the whole

healed by first intention, a little moisture from sero-pus being not sufficient to interfere with this process or delay it.

CASE III.

Pte. E., wounded July 4th, 1916. Amputated in uppermost third of thigh August 4th. The thigh was massive, and the patient was fat. The stump was very short. A large cauliflower granulation covered the end of the bone. This was surrounded by a broad band of cicatricial healing, and beyond this there were retracted and fleshy soft tissues.

On November 30th an incision was made along lines separating the skin and the cicatrix and the whole cicatrix and the granulation mass dissected off in one piece. On separating the cauliflower granulations a ring sequestrum was struck, and this was separated also. The skin and subcutaneous tissues were freely dissected up to allow of sufficient flap area to cover so large an exposed area and the protruding bone. This was accomplished, and two sets of button-sutures were put in. The skin edges were closely sutured as for a clean operation, and two small drainage tubes were put in at opposite angles in the wound.

The whole of these extensive edges healed by first intention, except the drainage tube openings, which united by second intention. The button-sutures were removed on the twelfth day, two days after the last of the skin stitches.

On the thirteenth day, all the edges having been firmly united, the temperature rose, there was much pain, and fluctuation appeared at the outer angle of the stump. So securely were the edges united even over this area that neither a sinus forceps nor a sharp probe was able to penetrate the cicatrix, and the abscess had to be opened along the line of union by a sharp-pointed bistoury in the ordinary way.

After three days this abscess evacuated, and the whole was securely united on the twentieth day. The man says his stump is lengthened, which is true. It is lengthened by the thickness of the skin and subcutaneous tissues covering the end of the bone.

CASE IV.

Pte. W. Amputated through lowest third of thigh. On arrival at hospital the end of the bone covered by granulations protruded about $\frac{1}{2}$ in. beyond the epithelial margin of new skin, and the band of new cicatrix was about $\frac{3}{4}$ in. wide. The skin and soft tissues were much retracted.

On November 11th, two elliptical incisions were made in front and at back of the protruding bone, and about two inches of bone was dissected out and removed. Similar treatment to the above was followed. This stump suppurated badly. The temperature was high, the pain was considerable, and the stump swelled considerably, putting much tension on all the sutures, so much so that the buttons of the button-sutures were half buried in the skin. Pus welled out from between the skin stitches and from the drainage tube openings. But the button-sutures stood the test, and the edges united by the second intention. The two tube openings and one central point where a small tube had been put on the fourth day showed granulation points of the size of split peas for several days longer, and then healed over on the twentieth day, and he left for a week's leave on the twenty-first day.

In the absence of button-sutures all the above cases would have hopelessly broken down, and the last state would have been worse than the first—the bone shorter, the granulating surfaces greater, and convalescence much protracted.

There are two factors that favour union in this method of reamputation. One is the increase in general vascularity that follows primary amputation. The largest vessels atrophy, but the small ones dilate. This dilatation of the numerous small blood vessels makes provision for a more general blood supply throughout the operation area, and guarantees a higher vitality. The pressure of the buttons is therefore of little or no consequence.

The other factor is that the skin and muscular tissues have already contracted to their maximum. There is little fear, therefore, of a further contraction when the attachments that have followed the primary amputation are disturbed by the reamputation. Shorter flaps will therefore suffice, and the "pull" over the end of the bone exerted against the button-sutures is less than one would suppose.

A consideration of these points would lead one to suggest:

1. Early reamputation and the saving of weeks of painful and tedious healing.
2. The control of bony proliferation, the avoidance of spurs, and the protection of the bone-end from infection, by careful technique in the treatment of the periosteum.
3. The covering of the end of the bone with muscle fascia and skin in such a way as to (a) approach the normal heel as a model and (b) provide for the most distant muscle attachments possible.
4. The use of button-sutures in every case of primary and secondary amputation where the flaps are large and the skin is stitched, in order to (a) keep severed muscles and tendons as nearly as possible

in apposition, (b) give immunity from the results of suppuration if it occur, (c) prevent haemorrhage between the flaps, (d) give the minimum area of flaps and the maximum length of stump where shortness is a locomotive disability.

A METHOD OF FLAPLESS AMPUTATION, WITH SUBCUTANEOUS DIVISION OF THE BONE AT A HIGHER LEVEL.

By W. SAMPSON HANDLEY, M.S., F.R.C.S.,

CAPTAIN R.A.M.C.(T.),

3RD LONDON GENERAL HOSPITAL, WANDSWORTH.

THE guillotine method of amputation as practised during the present war conveys at the first glance an impression of brutal simplicity which carries one back to the primitive ages. Nevertheless, it is probable that this method is one of the most valuable innovations the war has brought forth, and that for certain conditions it is the Omega as well as the Alpha of the subject of amputation. Its introducer, Captain Fitzmaurice Kelly,¹ is to be congratulated on his clear vision and courage. The main advantage gained by the method is that it exposes to infection the absolute minimum of raw surface.

The method is, however, attended by certain disadvantages and inconveniences. In some cases the skin eventually succeeds in spreading over and covering the exposed end of the bone. But even in these rare and favourable cases the bone is adherent to the skin. In the majority of cases the exposed end of the bone undergoes necrosis, owing to a simple acute osteomyelitis extending a little up the medullary canal. After the separation of the necrosed fragment a really good stump might conceivably result. But in point of fact the end of the bone always becomes adherent to the skin. Two cases recently under my care presented very similar conditions, and may be taken as typical. A bare necrosed piece of bone, still continuous with the living portion of the bone, projected from a raw, granulating surface corresponding to the original section of the limb. This surface was much smaller than the original cross-section owing to the spread of epithelium over the end of the stump and the contraction which always accompanies this process. In the neighbourhood of the bone this layer of granulation tissue becomes calcified or ossified almost up to its free surface, and adhesion of the bone to the skin is the inevitable result. Thus, in nearly all cases of guillotine amputation a secondary operation is imperative. The object of this paper is to suggest the trial of a method which, while retaining all the important advantages of the guillotine method, will obviate the necessity of a secondary operation. It is also, I think, the best way of doing the secondary amputation in cases previously submitted to the Kelly method, and with such cases I propose first to deal.

Secondary Amputation Following the Kelly Amputation.

In such cases it is necessary (a) to remove such a length of bone that an adequate covering of soft tissue is provided for what remains. (b) To excise the calcified granulations, which do not afford a suitable bed for the spreading epithelium. If calcified granulated tissues are allowed to remain, it is certain that ultimately the skin will be adherent to the end of the bone. (c) To do what is necessary with minimum exposure of fresh raw surfaces, since all these cases are necessarily accompanied by sepsis.

It is obvious that a formal flap amputation is unnecessarily extravagant and that it fails to fulfil the third requirement of a minimum exposure of fresh raw surface. This method, therefore, need not further be considered.

In the first case upon which I operated I made two lateral cuts upwards through the soft tissue at the side of the stump, thus fashioning two rough flaps. The bone was sawn through at the base of these flaps and they were then brought together by a few points of suture. This operation was followed by an alarming febrile disturbance, which, however, subsided in a few days. Its ultimate result was not satisfactory, for the skin was adherent to the bone. I had omitted to observe the second requirement—namely, to remove the ossified granulation tissue

FIG. 4.—Pte. W., four days after reamputation.

SIR WILLIAM J. COLLINS: FRAGMENT OF SHELL CASING EMBEDDED IN ORBIT.

FIG. 1.—Side view.

FIG. 2.—Front view.

FIG. 1.—Guillotine amputation of thigh, showing extreme retraction. The patient was admitted under the writer's care to the 3rd London General Hospital several weeks after the primary operation in France. A plaster extension would probably have prevented much of the retraction.

FIG. 2.—Complete healing of a flapless amputation. Note the close adhesion of the skin to the bone at the end of the stump. A secondary operation was necessary. Photographs kindly lent by Mr. Edred M. Corner, under whose care the case was admitted at the King George Hospital.

FIG. 3.—Guillotine amputation of the arm performed about six weeks before the photographs were taken. From a case under the care of Mr. Edred M. Corner.

FIG. 4.—Illustrating first stage of amputation of the thigh—the subcutaneous division of the bone.

FIG. 5.—Final stage of removal of limb. The assistant pulling strongly on the limb withdraws it from the stump almost like a cork from a bottle, the operator meantime dividing the muscular attachments to the bone.

FIG. 6.—Guillotine amputation of the thigh. Secondary amputation by the Gigli saw method. The stump nearly healed. The depressed cicatrices of the Gigli saw punctures are well shown. The stump is soundly healed with very little retraction. From a case under the author's care at the 3rd London General Hospital, Wandsworth. Drawing by Private E. Martin, R.A.M.C.

round the projecting necrotic bit of bone. Shortly afterwards I was faced by the same problem again—a guillotine amputation of the thigh about the middle, with projection of the necrotic end of the femur. It seemed feasible to minimize the exposure of raw surface by dividing the bone at the selected level by a Gigli saw. Two punctures were made at the end of the bone at the outer side of the limb, separated by about one-third of its circumference. Each of these punctures was situated four inches above the end of the stump. Through one of them a curved pair of forceps was introduced closed, and was insinuated round the bone until it was able to seize the end of the Gigli saw introduced through the other puncture. The pair of forceps was then withdrawn, bringing with it the saw. The bone was now divided, care being taken not to rasp the soft tissues. It would be possible to employ a pair of tubular guards to prevent the saw from bruising the soft tissues, but this is a refinement which is not essential. The punctures are made on the side of the limb remote from the main artery so as to avoid all risk of injury to the large vessels by the action of the saw. The end of the bone was now seized by lion forceps and with the aid of a periosteal elevator was easily separated from the soft tissues and removed. It only remained to excise the layer of calcified granulated tissue and to insert one or two sutures, making ample provision for drainage.

In this case there was only slight febrile reaction, and healing was rapid and satisfactory. The healing is now nearly complete, and the soft tissues are not adherent to the bone—in fact, the stump is very satisfactory. I venture to bring forth this method as being probably the best secondary operation for cases of guillotine amputation.

Division of the Operation into Two Stages in Exhausted Patients.

In patients exhausted by long-continued suppuration it may even be advisable to perform the little operation in two stages. The first stage is the subcutaneous division of the bone at the selected level. This operation should run an aseptic course. In a few days the ends of the marrow canal will be sealed by a layer of granulation tissue, and the isolated distal end of the bone can be removed with a minimum risk of osteomyelitis in the proximal end.

Amputation with Subcutaneous Bone Division as a Substitute for the Flapless Method.

It is evident that the method could be used for primary amputations, and I have successfully employed it on several occasions. The case now to be recorded illustrates its use.

On July 31st, 1915, I was asked by Dr. Erskine of Epping to see with him in consultation Miss X., a Red Cross nurse. Dr. Erskine informed me that when he first saw her, on July 25th, she was suffering from pain and swelling of the left thumb. Between July 21st and 25th she had been on duty each night at the hospital. On the night of July 24th she had acute pain in the thumb and felt ill, and the following morning, when Dr. Erskine was called in, the thumb was very inflamed and septic. The condition became worse and the inflammation spread to the forearm. When I saw her on July 31st there was extensive suppuration between the muscular planes of the forearm, and the patient was in a high fever and seriously ill. I judged that an attempt could safely be made to save the arm, and, after amputating the distal phalanx of the thumb, I made many free incisions of the forearm as high as the elbow and secured very free drainage. Temporary improvement occurred, but the patient again became worse, in spite of vigorous and able treatment by Dr. Erskine, and on August 7th I saw her again. In a specimen of blood taken on this date pure growth of streptococcus was obtained, and it appeared imperative, in view of this examination, to amputate the arm. This was done on August 12th through the middle of the humerus.

The amputation was performed by the method described in this paper. Two punctures, separated by one-third of the circumference of the arm, were made down to the humerus at the level selected for the saw cut. A Gigli saw was passed round the bone by the manoeuvre already described, and then the bone was divided. The soft tissues were now divided circularly at a lower level, the muscles being cut rather shorter than the skin. A few touches of the knife now sufficed to detach the muscle from the bone up to the point where it had been sawn.

The amputation wound suppurated freely; and this is not surprising in view of the infection of the blood which was known to be present. From the time of the operation the septic symptoms rapidly subsided, the temperature fell, and the patient made a good recovery.

In the healed stump the two punctured tracks made for the introduction of the saw are represented by two puckered

dimples on the skin. Evidently the band of fibrous tissues attaches the skin to the bone along the course of the tracks. This might be held as a disadvantage of the method, but I believe in reality it is an advantage, for these two bands of fibrous tissue serve during the healing of the stump to prevent retraction of the soft parts and exposure of the end of the bone. The method also has the advantage that the bone is divided as the first step in the operation. The length of the circular cuff of soft tissue required to cover it can then be precisely calculated. In the ordinary methods of amputation it is very easy to make the mistake of dividing the bone lower than was intended, especially if the assistant does not retract the soft tissues vigorously. The operator then finds that he has provided inadequate covering for the end of the bone.

I am inclined to think that this method may usefully replace the guillotine operation except in cases where extreme rapidity is required, and that in this way the necessity for secondary operation on guillotine stumps may in future be avoided.

The important object of the guillotine operation is to reduce raw surface to a minimum, and in this respect the method described in this paper is practically as advantageous. I trust, therefore, that the amputation method here described may receive a trial at the front. The situations where the method is applicable are in the thigh and the upper arm. It is possible that the method may be extended to the forearm and leg, but, owing to the presence of two bones in these situations, and to the relative thinness and easy retraction of the covering of soft tissues, the ordinary methods of amputation would seem to be preferable. The advantages of the method come out most strongly in amputations through the femur, and I believe that in this situation the method will supersede all others, not only on the grounds of simplicity, but also because the resulting stump is well-cushioned and non-retractile. In these respects I claim that the stump is perhaps better than can be obtained by any other method.

The passing of the Gigli saw round the bone may be difficult if the tissues are stiff and rigid from inflammatory infiltration. In these circumstances a suggestion of my friend Mr. Lawrie McGavin may be adopted, namely, to divide the bone subcutaneously by an Adams's saw. At the present time it is difficult to obtain efficient Gigli saws, since most of them before the war were made by an enemy firm, and some of those now upon the market do not cut hard bone very easily. In situations where the main artery lies close to the bone, the use of an Adams's saw requires care, and the rule should be to cut towards the artery and to fracture the last portion of the bone.

The skin should be retracted before the muscles are divided.

The only superiority of the flap amputation over the circular amputation is that it affords access for division of the bone at such a high level that a plentiful covering of soft parts is assured to the stump. In such a fleshy part as the thigh long flaps are necessary for this purpose, and the severity of the operation is thereby considerably increased. The method I have described is attended by the minimum of shock, haemorrhage, and division of tissue, virtues it shares with the Kelly method, while averting the necessity of any secondary operation.

¹ M. Fitzmaurice Kelly: The Flapless Amputation. *British Journal of Surgery*, April 16th, p. 676.

THE library of the College of Physicians of Philadelphia at the end of 1916 contained over 115,000 bound volumes, and nearly as many unbound theses and pamphlets. A considerable falling off was noted in 1915 in the number of books published in the French and German languages, and in Great Britain. During 1916 there was a relative increase in the case of Great Britain and a greater diminution in German publications. This, as is pointed out, is not to be taken as an indication of the number of books published. One of the features of the library are study-rooms, where a Fellow engaged in some particular research can work in peace and leave the books he is using from day to day. The popularity of these rooms is increasing. The librarian, Mr. C. P. Fisher, laments the difficulty of excluding dust from his stacks and shelves. The dust contains a large percentage of soot, which cannot be removed entirely even with a high-power vacuum cleaner. It is thought that electric lighting, combined with forced ventilation, and windows as nearly air-tight as possible, will afford a remedy.

A NOTE ON THE THOMAS SPLINT FOR FRACTURES OF THE FEMUR.

BY

CAPTAIN W. RANKIN, R.A.M.C.,

MEDICAL OFFICER IN CHARGE OF SURGICAL DIVISION,
No. — HOSPITAL, B.E.F.

To many surgeons the Thomas splint for fractures of the thigh is one of the "finds" which they will take back with them into civil practice, if they are lucky enough to reach that desired haven. Nearly every fractured femur travels to the base now in a Thomas splint, and this universal adoption is its greatest testimonial.

Too little care is taken in the method of use, however, and in no case, out of a very large number coming under my observation, has the fixation been such that I felt justified in passing the patient along without completely readjusting the splint. Badly fitting splints, with wrong material for slings and poor extension, improperly fixed, tend to bring a first class and extremely simple and good method into disrepute. Accordingly an endeavour is here made to illustrate and describe a technique which has proved satisfactory and has given good results.

The Splint and Slings.

The splint must be of a suitable size. The ring must not be too much padded. Some rings are padded so as to make it impossible for the patient to pass urine because of direct pressure on the urethra, and also make the use of a bedpan very difficult.

The slings must be made of a suitable material. Calico, linen, and strong flannel have all proved satisfactory. Gauze, gauze bandages, and perforated zinc have proved unsatisfactory.

Three different types of slings are illustrated (Figs. I, II, and III). Linen, calico, or flannel may be used.

FIG. I.—Slings prepared in advance: stocked in three sizes.

FIG. II.—Alternative methods of using a triangular bandage folded up into short slings of varying breadth.

FIG. III.—Alternative method with double layer of linen, calico, or flannel material. Loosely woven bandages and gauze are quite unsuitable. S, Safety-pin.

The breadth of the sling must be properly regulated. Triangular bandages also can always be obtained. The special slings illustrated in Fig. I (1, 2, and 3) require

previous preparation, and should be stocked in three sizes. The wooden rods (w) may be shaped from pieces of Gooch splinting, so that all the necessary materials are easily had. Tape, strong string, and good strong safety-pins complete the armamentarium.

The Extension Bands.

No adhesive strapping which I have tried, and I have tried many, has proved satisfactory. But the problem is perfectly solved by making use of a double layer of ordinary white gauze as it is unwound from the package, snugly bandaged with a flannel bandage to the limb which has been previously well smeared with Sinclair's glue.¹ (Mastisol is reported to act well also.) Where possible, the extension is always carried above the knee, and when it has been properly applied there will be no need to remove it for weeks. In no case in which I have used the glue has any skin irritation arisen. Care, however, must be taken to prevent pressure on prominent points, and the glue must stop well short of the ankle. As an extra precaution, a layer of gamgee tissue may be bandaged on to the ankle so that it will take all direct pressure off the malleoli.

The "give" in the extension bands requires to be corrected daily, and in order to do this without completely loosening the bands I make use of a method illustrated in Figs. IV and V. The long tail of one of the bands (A) is

FIG. IV.

FIG. V.

FIG. IV and V.—A method of keeping the extension up in using the Thomas splint. A, Long tail. B, Crossing. C, A reef knot is tied here in Fig. IV, one strap having come below and the other above the splint. In Fig. V a slip-knot is tied so that the daily adjustment may be easily done.

slipped through above the crossing (B) and pulled well down. Thus all the slack is taken up and the quadrilateral space is converted into a triangular one with the base toward the sole of the foot. A slip knot is then tied at the point C with the tail of the other extension band, and each morning, or whenever it is found necessary, it is the easiest matter to take up the slack and retie the bow. In this way the extension is kept up perfectly.

The last sling is put well behind the ankle and the foot left unsupported, so that the patient may keep the ankle-joint exercised. I have had no reason to regret this, or to adopt any foot fixation when dealing with fractures of the thigh. For all of the so-called "improvements" and "modifications" of the Thomas splint, in the way of spats and mechanical extension producers, etc., there is but one fitting use in my opinion, and that is to make a bonfire on which to burn the originators.

I desire to express my thanks to Lieut.-Colonel E. C. Hayes, R.A.M.C., for permission to publish this note, and to Major G. W. Crile, U.S.A., and Major W. E. Lower, U.S.A., American Base Hospital, for kindly getting their artist to make the excellent illustrations.

DAKIN'S "DICHLORAMINE-T" IN THE TREATMENT OF THE WOUNDS OF WAR.

By JOSHUA E. SWEET, A.M., M.D., F.A.C.S.,

PROFESSOR OF SURGICAL RESEARCH, UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA, PA.; CAPTAIN, MEDICAL RESERVE CORPS, UNITED STATES ARMY.

UNITED STATES ARMY BASE HOSPITAL No. 10, FRANCE.

(Report to the Medical Research Committee.)

[AFTER a short preliminary discussion of the advantages and disadvantages of such chlorine-containing solutions as eusol, Dakin's solution, and Daufresne's modifications thereof, Professor Sweet states that Dr. Dakin entrusted the honour of testing the surgical value of dichloramine-T (toluene-para-sulphodichloramine), described by Dunham and Dakin in the BRITISH MEDICAL JOURNAL of June 30th, to Dr. Walter E. Lee, of the Pennsylvania Hospital, and himself. The results obtained there are being published in America (*Journal of the American Medical Association*), but Professor Sweet, working with the United States Army Base Hospital No. 10, has since been able to test the effect of the new preparation on war wounds in a British general hospital in France. With regard to the results there he reports as follows:]

We have treated some eighty patients with Dakin's "dichloramine-T"; some have been old cases with foreign bodies lying in the bone, and suppuration did not stop until the foreign body was removed. Fresh cases, in which enough integument was left to permit it, have been treated with dichloramine once and immediately closed, and have healed by secondary intention. Sixteen cases, old and fresh, were cultured after treatment with "dichloramine-T" for varying periods, of which eleven gave no growth whatever; of the five in which a growth appeared, four were old cases of deep bone involvement; the only growth was the *Staphylococcus aureus* in four cases and in one case the *pyocyaneus*.

The wounds fill rapidly with granulation tissue of healthy colour, which exhibits no tendency to exuberant growth and no tendency to become water-soaked and indolent; the skin edges grow in very rapidly.

These results are no different from those which can be obtained by other methods, and no one would believe them if they were any better. Let me say, therefore, that the surgeons of the unit are agreed that the wounds treated by "dichloramine-T" are in every way as satisfactory as they have ever seen under any method; and two of our surgeons have had previous experience in France, while all are surgeons of long experience in civil practice.

The results along other lines are capable of more definite demonstration, and it is on these that I would lay the most emphasis.

The new "dichloramine" solution is made by dissolving the crystals of "dichloramine-T" in chlorinated eucalyptol and then diluting this solution by the addition of chlorinated paraffin oil. It is best applied by an oil spray, an ordinary hard rubber or all-glass atomizer being the most practical method. Metal atomizers are not suitable, since the metal is attacked by the chlorine. This oily solution presents the first great advantage—the dressings do not stick to the wound and the entire act of dressing is relatively painless. The gauze does not have to be separated from the granulations by soaking. It is therefore not even necessary in the average wound to place a waterproof protective covering over the bed-linen while dressing, and the necessity of moving the part or the patient is obviated. The old dressing is simply lifted off, and the wound sprayed; the force of the spray will dislodge sloughs, and the wound is covered with a fresh dressing. It is evident that a very important saving of time results from this simplicity of dressing. One surgeon has repeatedly dressed thirty wounds in ninety minutes—an average of three minutes to each dressing. These figures and the figures to be given later, refer to the acute wards, where the patients are all bed patients.

The solution contains enough available antiseptic so that one dressing every twenty-four hours is ample for large, deep wounds, and one dressing every forty-eight or seventy-two hours is enough for the simple or more superficial wounds. Since the solution contains so much

available chlorine and does not have to be renewed every few hours, the use of the Carrel tube is entirely done away with. The oily solution of "dichloramine-T" creeps into all the wound crevices and corners, and it can be readily introduced into sinuses by means of a cotton swab dipped into the solution.

The amount of this new solution needed for wound dressing should be emphasized. At first thought it would seem that a solution containing oil of eucalyptus and paraffin oil would be far too expensive for general use in comparison with eusol. Forty-two wounds were dressed by one surgeon with 35 c.cm.; another surgeon dressed 154 wounds with 115 c.cm. These figures apply to the acute wards, and include many compound fractures and extensive buttock and thigh wounds. The fact that so little fluid has to be used, and that therefore only the wound discharge has to be cared for, results in a tremendous saving of gauze and cotton. I give below a table of the results of a comparison of the amounts of gauze and cotton used during different periods in the four acute surgical wards of the hospital. Each ward is in charge of surgeons of equal skill, and all trained in the same hospital; the nurses are also all graduates of the same hospital training school; in other words, the comparison is not between workers trained in different schools of surgical technique.

TABLE I.—Gauze and Cotton-wool Used July 5th, 1917.

Wards.	Gauze (6-yard rolls).	Cotton (1-yard rolls).	Treatment.	No. of Patients.
1	12	2.5	Eusol	23
2	10	4	Eusol	22
3	3.5	2.5	Dichloramine-T	23
4	6	2.5	Eusol	25

Taking a longer period, the amount of gauze and cotton used in seven days by three of the acute surgical wards is given in Table II. Ward 2 changed during this period from the use of eusol to the use of dichloramine-T; the figures from this ward are therefore not available. The number of patients was the same in the three wards, and the proportion of relatively slight and extensive wounds in each ward was the same.

TABLE II.—Gauze and Cotton-wool Used from July 4th to July 10th, 1917, inclusive.

Ward.	Gauze (6-yard rolls).	Cotton (1-yard rolls).	Treatment.
1	72	38.5	Eusol.
3	33	7	Dichloramine-T.
4	45	18	Eusol.

This saving of material is of importance in several ways. Not only does it effect a saving of labour from the cotton field to the hospital, not only a saving of transport, but an important saving in the hospital itself; the time taken by the nurses in the preparation and sterilization of material can be utilized for the care of the patients, and to this can be added the saving in time, labour, and material by doing away entirely with the need for the Carrel tubes. The need for so little solution in wound dressing, and the fact that the dressing need only be sufficient to care for the wound discharge means that the bed-linen is not wet, with a consequent saving in the moving of the wounded, and an increase in their comfort and well-being.

The dichloramine-T solution, like all the other chlorine compounds, is a very active lymphagogue in fresh wounds, and the amount of wound excretion may be considerable. The lymphagogic effect may be directly watched in suitable wounds. As granulation tissue develops, the lymph discharge greatly decreases until the wound becomes comparatively dry. The dichloramine-T also possesses to a marked degree the characteristic power of the chlorine solutions in aiding the digestion and removal of necrotic sloughing tissues. The new solution seems more effective in cleaning up sloughing tissue than the older chlorine compounds. While the majority of our cases come from

the casually clearing station in excellent, clean condition, a sufficient number have reached us with necrotic tissue in the wound amply to satisfy us of the rapidity with which the dead tissue is freed under the dichloramine-T. The tendency to secondary haemorrhage is certainly not increased. We have had only one secondary haemorrhage in the series, which includes a number of deep buttock wounds, and cases of exposed great arteries of the arm and leg.

The solution is not irritating to the skin or mucous membrane, except possibly in the rare individual who possesses an idiosyncrasy to the eucalyptus oil. Such individuals have been reported in dermatological literature. Among the patients treated here we have encountered only one case of dermatitis, but since it did not develop until after two weeks' use of the solution and was accompanied by high temperature, it is not clear that it should be ascribed to the eucalyptus oil or to the well-known action of wound excretion.

The constituents of the solution are stable although the final combination is not indefinitely stable nor can it be exposed to strong light. It is easily prepared from the constituents. The dichloramine-T which I have was put up in packages of 10 grams each; the content of one package is dissolved in 75 c.cm. of chlorinated eucalyptol and diluted with equal parts of chlorinated paraffin oil as needed, making, therefore, approximately a 6.5 per cent. solution of dichloramine-T.

The first application of the solution to a fresh wound produces a smarting or burning sensation, which passes away in a very few minutes; in some individuals this seems quite severe, but I have yet to see the patient who does not prefer this slight smarting to the real pain of removing a wet dressing which has dried around the edge of the wound. After the second or third application this smarting sensation on applying the solution seems to have disappeared.

Since the time to treat an infection is before the infection starts, it is hoped that the dichloramine-T solution can be given an early trial at the field ambulance and casualty clearing stations.

Conclusions.

Dakin's "dichloramine-T," in solution in eucalyptol and paraffin oil, is of great advantage in wound treatment—even if the final results in wound healing were no better, because—

1. It saves the pain of wound dressing.
2. It effects an appreciable saving of dressing material.
3. The amount of solution needed is of small bulk.
4. The number of wounds which a surgeon can dress in a given time is far greater than by any other method.
5. The elimination of the Carrel tube simplifies the dressing and the problem of transportation of the wounded.
6. The elimination of the Carrel tube saves the time taken by the nurse for the periodic flushing.

AN EXPEDITIOUS METHOD FOR THE STUDY OF ENTERIC STOOLS:

A REPORT ON THE EXAMINATION OF 1,200 SPECIMENS OF FAECES FOR ENTERIC ORGANISMS.

BY

F. B. BOWMAN, M.B. TORONTO, MAJOR C.A.M.C.,

OFFICER COMMANDING NO. 2 CANADIAN MOBILE LABORATORY.

(Report to the Medical Research Committee.)

DURING six months in 1916 the examinations of faeces for enteric organisms (*B. typhosus*, paratyphoid A and B) made at this laboratory numbered 1,200. No claim for originality is made for the technique adopted, and the procedure is reported as having been, in my experience, efficient as well as simple. A minimum of culture media, glass-ware, etc., is required, and the culture media are easily prepared.

Nearly all the samples were sent from a hospital which admitted only patients convalescent from enteric fever or dysentery, and Army Council instructions in regard to the routine examinations were carried out carefully.

Each patient was given a numbered basin, and the specimen was obtained from this. We have always used

specimen containers (supplied by Messrs. Baird and Tatlock) consisting simply of small, wide-mouthed bottles, well stoppered with an ordinary cork, in the centre of which is fastened a small child's toy tin spoon, the whole enclosed in a wooden case.

Materials Required.

1. Peptone Water.

Peptone (Baird and Tatlock)	10.0
Sodium chloride	5.0
Water	1,000.0

To dissolve, place in autoclave for five minutes. Shake well, filter, and tube. Sterilize in autoclave at 15 lb. for fifteen minutes. Each tube should contain about 5 c.cm.

2. Endo's Medium.

Liebig's extract of beef	10.0
Sodium chloride	5.0
Peptone	10.0
Water	1,000.0

Dissolve in autoclave at 120° C. for five minutes. Add 30 grams of washed agar, and autoclave at 120° C. for fifteen minutes. Filter and neutralize to litmus. Add 10 c.cm. of a 10 per cent. solution of sodium bicarbonate and 10 grams of lactose. Place in steamer for one half-hour. When plates are to be poured, the above stock (1,000 c.cm.) should be melted and 5 c.cm. of alcoholic basic fuchsin solution (basic fuchsin 3 grams, alcohol 57 c.cm.) added, and 25 c.cm. of a 10 per cent. solution of sodium sulphite. Then steam for fifteen minutes and pour into plates. Allow to cool and store in the dark till ready for use.

By placing a circle of blotting paper in the lids of the Petri dishes before sterilizing them, all the water of condensation is absorbed; this aids greatly in making successful cultures.

3. Hiss Medium.

Liebig's extract	5.0
Sodium chloride	5.0
Distilled water	1,000.0

Dissolve in autoclave at 120° C. for five minutes, add 8 grams of washed agar and melt in autoclave at 130° C. for five minutes. Add 80 grams washed gelatine, dissolve and cool to 45° C. Clear with the white of one egg in the autoclave at 120° for five minutes, filter, and to filtrate add 1 per cent. of dextrose and sterilize in the steamer for one half-hour. Put about 5 c.cm. into each tube and sterilize in the steamer again. This medium at 37° C. remains quite solid, and will retain gas bells.

I have found that the following procedure saves twenty-four hours in the examination of suspected colonies.

The tubes containing the Hiss medium are placed upright in a basket in a basin containing ice water, and a few cubic centimetres of a fairly stiff plain agar is poured into each tube and the tube immediately sloped, producing the result shown in the diagram.

4. Standard Agglutinating Serums.—We have obtained these from the Royal Army Medical College, Millbank, and from the Standard's Laboratory, Oxford.

Procedure.

Each specimen is given a number and a peptone water tube the same number. A piece of faeces the size of a pea is removed with a wooden applicator from the specimen bottle and thoroughly emulsified in a tube of peptone water. Each specimen is allowed to stand about half an hour and is then ready for plating.

The Endo's medium having been poured, the plates should be a very faint pink in colour and as dry as possible. A curved glass rod is passed through a flame and when cool plunged into the peptone water emulsion and then removed. The lid of the Endo's plate is removed with the left hand, and while revolving the plate the glass rod is smeared from the centre to the margin like the spokes of a wheel; the same procedure should be carried out on a second plate without recharging the rod.

These plates are incubated overnight and examined for suspicious colonies. *B. coli* being an acid producer will appear as beautiful golden metallic-looking colonies, and streptococci as small crimson dots; any colonies grey in colour with no metallic lustre should be regarded as suspicious. These are fished off with a platinum needle and stab cultures made into the Hiss tubes, and at the same time streaks are made on the superimposed agar

A. Plain agar slope.
H. Hiss medium.

slopes. These are now placed in the incubator at 37° C. overnight. If any gas bubbles appear in the medium, the tube is discarded. If the stab shows a clean growth with no bubbles the tube is set aside for further examination.

Having arranged the suspicious cultures in a rack, the next procedure is the agglutination of these organisms to identify them definitely.

Different dilutions of the standard serums are made, say from 1 in 20 to 1 in 500. Drops of the serum in these different dilutions are placed on a clean slide and a small loop of twenty-four hour culture of the homologous organism is emulsified in the serum dilution. The slide is now rocked from side to side, and in a satisfactory dilution agglutination of the organisms should be seen easily in a few seconds. Each serum is tested in this way with each type organism, to learn the proper titre to use in testing the unknown cultures.

Having obtained the proper titre, the same procedure is adopted with regard to all the unknowns, and although in some instances agglutination reactions may overlap, the culture may be called positive and higher dilutions used in definitely determining the organisms as being "para" A or "para" B. An emulsion of *B. coli* should also be used each day as a control with each serum dilution.

Of 1,200 specimens examined from enteric convalescents, 45 were found positive for paratyphoid A, 12 positive for paratyphoid B, and 13 positive for typhoid bacilli. Two cases were definite carriers of paratyphoid A, and from these occasionally plates showed pure cultures of this organism.

Following the publication of the paper by Leitch,¹ who used brilliant green and telluric acid with excellent results, we began a series of experiments, using these substances in the peptone water; unfortunately, the cases were suddenly ordered to be sent elsewhere, and we could not continue the work, but 100 specimens were put through in this way, and one positive was found which had been overlooked by direct plating on Endo's medium.

In examining specimens of urine about 2 c.cm. is added to a melted Hiss tube, and plates are poured and smears made on Endo's medium at the same time. Suspicious colonies are then treated in the same way as the cultures from faeces.

Summary.

In a laboratory where pathological examinations of all kinds are asked for, and where a large amount of work is done with a small and sometimes inexperienced staff, a routine as uncomplicated as possible must be used. The procedure for examination of faeces as described here is not recommended as being the best, providing one has time to prepare other media, such as the different sugars; but where a large number of men may be waiting for release, the reports must be given in as short a time as possible, so long as this does not interfere with their reliability.

Endo's medium I have always found superior to any other for plating, and it is the most easily prepared. The slope agar Hiss tube is a valuable adjunct, and saves at least twenty-four hours in identifying a suspicious colony.

The results of these examinations would seem to compare favourably with those reported when other methods have been used.

June 1st, 1917.

REFERENCE.

¹ BRITISH MEDICAL JOURNAL, September 2nd, 1916, p. 317.

In 1913 (*Deut. med. Woch.*, March 15th, 1917) there were 620,455 deaths in Prussia—321,980 males and 298,475 females. In 1914 the deaths increased to 766,828 (males 449,645, females 317,183). The average relative mortality of males and females in the period 1886-1913 was as 109 to 100. According to this ratio, the deaths among males in 1914 should have been 345,729. By subtracting from this hypothetical figure the actual number of deaths among males in 1914, the figure 103,916 is obtained, representing the number of deaths due to the war. The death-rate per 1,000 in 1913 (not including stillbirths) was 14.9. In 1914 it had risen by 3.2 to 18.1. It was, however, almost as high (17.9) in 1906, and in 1905 it was higher (19.6).

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

DISORDERS AND DISEASES OF THE HEART IN SOLDIERS.

No one engaged in military medical work could fail to read with interest and advantage Sir T. Clifford Allbutt's article in the *BRITISH MEDICAL JOURNAL* of August 4th. The responsibility of estimating the degree of disability in cases labelled "D.A.H." (disordered action of the heart) and "V.D.H." (valvular disease of the heart) is no light one, and it has been some consolation to read Sir T. Clifford Allbutt's very modest statement in his article "Overstress of the Heart" (Allbutt and Rolleston's *System of Medicine*, 1909) that, after an experience dating from 1870, he still approached with diffidence the problem of distinguishing the "functionally fretful" from the "strained" heart. This attitude of a very eminent authority, one of the pioneers of investigation of "the soldier's heart," is in striking contrast to certain loose but confident opinions, as to diseases and disorders of the heart, expressed during the war.

No doubt undue importance was at one time attached to murmurs, and the value of concomitant physical signs and symptoms was not fully appreciated. Nevertheless one has viewed with uneasy suspicion Sir James Mackenzie's dictum that bruits may be disregarded (wherever they may be heard) in estimating capacity for military service. Safe enough in Sir James Mackenzie's hands, this doctrine seemed calculated to engender a too cheery optimism in practitioners called upon to form (without the polygraph or the electrocardiograph) a prognosis as to the patient's capacity for further military service. Moreover, it is a moot point whether the practitioner's duty ends with a prognosis "for the duration of the war." The patients in 90 per cent. of cases are young men, and they may claim not unreasonably that more remote effects of wear and tear demand consideration.

During the winter of 1916-17 I gave all the time I could spare to the investigation of myocardial efficiency in cases of "D.A.H." and "V.D.H." under my care, employing, in addition to the usual physical examination, Dr. Strickland Goodall's exercise-blood-pressure test, with certain modifications.¹ My results were embodied in a short paper, read before the Reading Pathological Society, and I showed charts in which the systolic and diastolic pressures, pulse, and respiration rates were recorded before and at intervals after exercise. I drew attention to the fact that in a considerable proportion of cases of "D.A.H." a murmur is audible, which in my opinion is too lightly dismissed as "functional," "haemic," "transitory." The murmur is systolic in time, and it is audible in the third, fourth, and fifth left intercostal spaces along the left border of the sternum—that is, in the tricuspid area. The cases presenting this murmur (and others in which it does not occur) show an increase upwards of superficial cardiac dullness in the left parasternal line; the dullness extends usually to the upper border of the third interspace. In most of these cases there is a variable degree of displacement of the apex beat outwards. It seems difficult to resist the conclusion that the murmur indicates dilatation of the right heart and regurgitation through the tricuspid valve. Sir T. Clifford Allbutt explains the importance of such murmurs, even when they are transitory, and he points out that "the efforts cast upon such a heart should not be immoderate"—in other words, the murmurs have a significance, and are not to be disregarded.

The important part played by infections in causing disability of the myocardium and rendering it liable to strain is duly emphasized in the article under consideration. Unfortunately, both in civil and military practice, the more remote effects of acute infections, apart from rheumatic fever, upon the myocardium are apt to be forgotten.

Reading.

GORDON LAMBERT.

In the correspondence in the *BRITISH MEDICAL JOURNAL* on soldier's heart it has been stated that the systolic murmur heard at the base over the pulmonary area is due, in the vast majority of cases, to the friction between the

¹ Dr. Strickland Goodall: The Estimation of Myocardial Efficiency, *BRITISH MEDICAL JOURNAL*, October 14th, 1916.

pulmonary artery and the chest wall or adjacent structures. I am in charge of a camp of over 2,000 lads under 19 undergoing military training, a large number of whom are classed in low categories, and I am much struck by the number of cases in which this systolic murmur occurs, and by the fact that it is generally associated with poor physique in lads who are undersized and showing bad or retarded development. It may be that their chests are smaller and the friction more likely to occur, but my impression is that although there are seldom signs of cyanosis, the under-development also applies to the heart itself, and that there is probably some relative or actual narrowing of the pulmonary artery, such as occurs in the commoner forms of congenital heart disease. Certainly the symptoms associated with D.A.H. (disordered action of the heart) are very common with these lads, and I have advised a more graduated course of physical training for some of them.

It would be very interesting if those who have had the opportunity of making *post-mortem* examinations on patients who have complained of symptoms of D.A.H. would report on the condition of the pulmonary artery and valve in these cases.

H. M. RAVEN,
Lieutenant R.A.M.C.

TREATMENT OF SCABIES.

I HAVE read with great interest the paper by Captain Clark and Captain Raper on the chlorine treatment of scabies, published in the BRITISH MEDICAL JOURNAL on July 28th.

My interest, however, was chiefly aroused by the details these medical officers give of the history and previous treatment in the fourteen selected cases. Six had already been treated by sulphur before they were subjected to the gassing process; four of these must have suffered from very severe sulphur dermatitis, for it is stated that they had received three months' sulphur treatment (Case 2); three months' treatment, probably irregularly (Case 4); many treatments with calcium sulphide during five months (Case 9); and sulphur treatment for two weeks (Case 12).

If Captain Clark and Captain Raper will try the effect of sulphur ointment applied for *three days only*, after a preliminary hot bath, they will find, if the details are properly carried out, that a cure of the scabies has been effected in practically every case.

Major R.A.M.C. (T.C.).

ADIPOCERE IN THE BODIES OF THE DROWNED.

THE dead body of a middle-aged man was recently recovered from the sea outside Milford Haven. The scalp, with skin of forehead and eyelids, were missing, also the lips; both forearms were absent. The boots and clothing were fairly well preserved. There was complete absence of all unpleasant smell or odour; the surface was white and covered with minute marine growth of barnacles. The tissues had, instead of disintegrating, undergone a change into adipocere, which covered chest, back, and abdomen like a solid case, and no doubt prevented escape of gas, etc.

It would be hard to answer the question, How long has this body been in the sea? I think much longer than might be supposed possible for a dead body to float—possibly for months. If it had not been for this formation of adipocere this body would have sunk long ago, and would not have been recovered.

I think it possible that this dead body will be in just as good preservation years hence as it is to-day. It was not possible to identify the individual.

Dale, Milford Haven. H. W. BERNARD,
Lieutenant R.A.M.C.

THE DETECTION OF DEAFNESS.

MEMBERS of medical boards occasionally meet with men who state that they are "stone-deaf" in one or both ears, and much more frequently men who state that they are "hard of hearing" in one or both ears. In a number of these cases the examiner suspects malingering, or at least an exaggeration of the deafness. The usual tests, such as the watch and the tuning-fork, take time, depend upon

the statement of the subject as to whether he hears them or not, and are therefore open to serious objections.

Some months ago, while examining with the speculum a man suffering from chronic otorrhoea, I noticed his eye blinking in the normal way, and it occurred to me to make use of this to discover simulation or exaggeration of deafness, because the act may be said to be involuntary.

I employed the following plan on the next subject, who stated that he was "very hard of hearing." First, I asked him which ear was the deafer, and then requested him firmly to close it with the index finger of the hand of the corresponding side. Next, standing on his opposite side, with my face about six or eight inches away from the other ear, and having pretended to examine the ear carefully for a few seconds, I whispered quickly, "Shut your eyes." He was a malingerer, and having been taken by surprise he closed them before he could take thought.

This method may also be employed as a ready, but perhaps a rough, test for varying degrees of deafness, by gradually raising one's voice or bringing one's mouth nearer the ear of the subject.

THE KING GEORGE V HOSPITAL.

LARGE FRAGMENT OF SHELL CASING EMBEDDED IN ORBIT;
FRACTURE OF ORBITAL WALL AND LACERATION OF
GLOBE: SUCCESSFUL REMOVAL AFTER LOCATION
BY X RAYS.

(By Sir WILLIAM J. COLLINS, M.P., K.C.V.O., M.S., M.D.,
B.Sc.Lond., F.R.C.S.)

PTE. G. A., aged 20, 54th Canadians, was admitted to King George's Hospital on October 24th, 1916. He was wounded on October 21st at Courcellette, he states, by "shrapnel." The left eye was markedly proptosed and apparently perforated, the tension being -2. There was great chemosis of the conjunctiva, some blood visible in the anterior chamber, and the fundus was unilluminable. An inch and a quarter behind the left external angular process was a small wound, with ecchymosed margins, and some subcutaneous blood clot. There was great tenderness of the eye and parts adjacent to the orbit. There was no perception of light. Temperature 100°; pulse 64. No other wound, and the other eye was normal.

A radiogram taken by Mr. Ironside Bruce showed a "large fragment of shell casing lying behind the eye in the upper part of the orbital space, the posterior wall of the space being involved." On October 27th, under chloroform administered by Mr. Harwood, after disinfection of the eye and wound, Sir William Collins enucleated the lacerated globe. With the index finger he located the piece of shell casing fairly firmly fixed into the orbital roof, while portions of bone, apparently from the great wing of the sphenoid, were extracted from the orbit. The fragment of shell was cautiously freed from surrounding semi-organized clot and periosteum, and then seized with sequester forceps and gently extracted. The wound in the temporal fossa had clearly been the site of entry, and some portions of the outer and upper wall of the orbit had been fractured. The impact of the fragment thus arrested in its course had, after penetration, been sufficient to rupture the upper and posterior part of the globe of the eye. Drainage tubes were inserted in both the orbit and the temporal wound, the edges of the latter having been excised. Convalescence was uninterrupted, and by the end of November the wound was healed, the socket healthy, and only some stiffness of the left temporalis muscle remained.

The piece of shell casing, erroneously but commonly described as "shrapnel," measured 17 mm. × 11 mm. × 8 mm., and was of the irregular contour shown in the accompanying radiograms (p. 245).

Reviews.

THE METHOD OF ENZYME ACTION.

THERE is no one man who has done more to advance our knowledge of enzymes and enzyme action than Professor Bayliss; by general consent he is acknowledged the foremost authority upon this subject. It must, however, be admitted that he writes for the trained physiologist, and that he credits his readers with a familiarity with the facts and theories of physical and colloid chemistry akin to his own deep knowledge of these branches of science. As a result, his writings are apt to be "caviare to the general." Hence the need of a monograph which shall place before the intelligent student and the medical man wishful to keep abreast of the physiology of to-day an account of present views regarding enzymes and their nature that can be followed without undue difficulty. The book on *The Method of Enzyme Action*, by Captain JAMES BEATTY, M.D., D.P.H., R.A.M.C.,¹ very largely fulfils the need; so largely, that when it is realized that the work is a *tour de force*, that it was written and sent to the press while the author was serving in the Near East, away from any library, it seems ungracious to call attention to any defects. Our criticism, let us assure him, is afforded in the belief that his little book will reach a second edition.

Having regard to the medical man whose training in physiological chemistry antedates the beginning of the century, there are sections which might with advantage be expanded. We refer more particularly to the important chapter upon hydrolysis and to the final chapter. In both instances what is needed is a full, reasoned presentation of material that is unfamiliar to the reader rather than what might be termed a succession of lecture headings, and Captain Beatty can easily provide this, as is shown by his clear presentation of the results of other workers upon catalysis, adsorption, colloids, and enzyme action. The summaries at the end of each chapter are most valuable.

Captain Beatty's own conclusions regarding the nature of enzyme reaction, while given with greater wealth of detail, appear to be somewhat akin to those formulated by Professor Adami in his recent Croonian lectures. It is a view which, as Euler points out, is receiving general acceptance in enzymology. Bayliss also agrees "that there is abundant evidence that a combination of some kind is formed between the enzyme and the substrate preparatory to the action of the former. There is also similar combination between enzyme and products." Captain Beatty holds that in solution there is a weakening of the bonds between the atoms comprising a salt, and that enzymes possess a double action—on the one hand a general or unspecific power of attraction of one or other of the free, or freed, hydrogen or hydroxyl ions existing in a water solution; on the other, a specific power of adsorbing a particular substrate. It is in the promotion of this hydrolysis of the substrate—or synthesis, for the reversibility of enzyme action is admitted—that we have the essential nature of enzyme action.

Captain Beatty doubts if there be actual chemical union between enzyme and substrate; he is prepared to admit that there is "molecular combination." But if, as he admits, in solution there is weakening of the bonds between the components of a salt, the demarcation between chemical combination and molecular combination in a solution must in itself be somewhat loose. Briefly, his hypothesis is based (1) on the possibility of combination between molecules in a watery solution, and (2) the hypothesis that this molecular combination loosens the internal bonds in one or both of the combining molecules. We would suggest to Captain Beatty that in a future edition he affords graphic representations of the different stages of the process as conceived by him, and that in his formulae also he represents the enzyme by some conventional sign so that what he regards as the exact relationship in the various stages be more clearly grasped. For example, we are still uncertain as to what he regards as the course of events in proteolysis—whether

the enzyme first withdraws a peptone radicle from the compound protein, which radicle then undergoes hydrolysis, or whether hydrolysis (or synthesis) through the agency of the enzyme is the first stage, the very act of hydrolysis in itself weakening the bond between a particular peptone radicle and the remainder of the compound protein molecule, so that this *ipso facto* floats free from its companions and *ipso facto* becomes loosened from the enzyme, which now is free to repeat the process. To repeat, Captain Beatty has performed a distinct service in bringing together much valuable material which it is not easy to obtain in a collected form elsewhere; evidently he is on the threshold of a fertile hypothesis. But, for the sake of lucidity, his material in parts needs expansion.

NOTES ON BOOKS.

THE forty-first volume of the *Transactions of the American Gynecological Society*² is of special interest in that its first 428 pages are devoted to the relation of syphilis to obstetrics and diseases of women independent of pregnancy, parturition, and the puerperium. The effects of syphilis on the middle and upper part of the female genital tract remain ill defined. Hence, perhaps, the profession will award special value to Drs. Gellhorn and Ehrenfest's paper on syphilis in the internal genital organs in the female, and Dr. Charles G. Norris's on syphilis of the body of the uterus. The former authors allow that our actual knowledge about syphilitic lesions of the uterine body is extremely meagre, while Dr. Norris observes that it is remarkable how seldom the disease has been observed in the uterus above the cervix. The treatment of cancer forms the subject of several instructive monographs in the volume.

MEDICAL AND SURGICAL APPLIANCES.

X-RAY FILMS.

FILMS have been employed in x-ray work for a long time but hitherto have not displaced plates. A new type of film has been placed on the market by Austin-Edwards Limited, Warwick, England, and from the results of the trials so far made we are able to say that these films are good, and will be found to give very satisfactory results if proper precautions in handling them are observed.

The film is coated upon both sides of the celluloid support; the thickness of the celluloid is only $\frac{1}{16}$ of a millimetre, so that the sharpness of the photograph, which consists of two negatives, one on each side of this flexible support, is excellent. They appear to be about twice as rapid as the best x-ray plates, and if placed in the usual cassettes with a reinforcing screen on both sides they ought to prove the fastest on the market. They have the advantage of lightness and are unbreakable. They are supplied in black envelopes with a cardboard support, so that they can be handled in the same way as glass plates. In development care must be taken not to injure one or other of the gelatine films, because, unlike a plate, which is always developed with the gelatine film uppermost, here, perforce, one of the sensitive films has to be below; it must be thoroughly soaked in water for a few moments before being carefully floated into the developer, and repeatedly and carefully turned so as to get even development. For the same reason care has to be taken in drying these films. As sent out, they have two small holes already punched in two corners, which allow pins to be passed through for support. Full directions are printed on the cover of the boxes, and there is no difficulty in carrying them out. For stout patients and in deep, difficult parts of the body these films ought to prove of great use, and specially for extremely rapid exposures. Sandwiched between two reinforcing screens and well pressed together they ought to prove of exceptional value. For use in this way they would, of course, have to be taken out of their envelopes and put into cassettes. All can be done in the dark room as usual. As has been indicated, the main difficulty likely to be encountered is in developing, and unless care is taken there will be a risk of spoiling the negative. The agents for the sale of these films are Houghtons, Ltd., 88, High Holborn, W.C., and Glasgow.

¹ *The Method of Enzyme Action*. By James Beatty, M.A., M.D., D.P.H. With Introduction by Professor E. H. Starling, M.D., Sc.D., F.R.S. London: J. and A. Churchill, 1917. (Demy 8vo, pp. 145. 5s. net.)

THE ROYAL ARMY MEDICAL CORPS AND ITS WORK.

(Concluded from p. 234.)

CASUALTY CLEARING STATIONS.

THE railroad hospital or casualty clearing station may theoretically be described in several ways.

1. As the administrative junction between the lower limit of the collecting zone or front with the upper limit of the evacuating zone or lines of communications.

2. As the focal point to which converge all roads leading from the front, and from which diverge all roads leading to the base.

3. As the spot where road transport ends and railway or analogous transport begins.

4. As the place where all casualties collected from main dressing stations are deposited until the moment comes for their transport through the evacuating zone to the base or distributing zone.

In practice the casualty clearing stations justify all four definitions more or less precisely, but the fact is rather obscured by their multiplicity and the great length of the front. It will be found, however, that whatever may be the position of a given casualty clearing station there are always roads that lead to it from the front, and that, however far beyond the general level of the evacuating zone it may seem to lie, it preserves its theoretical relation thereto, because a tongue or spur has been thrust up to meet it.

SELECTION OF SITE.

Two of the essentials in the selection of a site for a casualty clearing station are ready access from the front for motor convoys and free communication with the base by ambulance trains. A third is plenty of room for the necessary tents or huts, a free water supply, and safety from any but extreme range artillery fire. To find a suitable site is often difficult. Adequate room and protection from artillery fire are generally easy to secure, and water can be piped from a considerable distance, but to find a place which, besides being suitable in other respects, is readily accessible by road from the main dressing stations concerned, and lends itself to evacuation to the base by train, is much more difficult. It is a problem, in fact, which can often be solved only by running a special branch railway up to the proposed site, or by choosing a site which is on an existing railway but at a considerable distance from the main dressing stations that have to be cleared.

The first plan involves heavy expenditure of time and labour, and is usually adopted only when later on the site may be useful for some other purpose, or when the branch line can be made to serve more than one end.

The second solution is therefore the commoner, but it is to be remembered that accessibility and shortness of distance as the crow flies are not interchangeable terms. The old proverb, "The longest way round is the shortest way home," has a particular application to the transport of wounded men. Once a man is in a well-sprung pneumatic-tired ambulance car the exact distance that he travels is of less importance than the character of the roads over which he is borne. Hence, independently of all other considerations, a site which communicates with the front by good roads is always to be preferred, even if the distance to be traversed be treble, to one which can be reached only by lanes and cart-tracks.

This is one reason why the casualty clearing stations as a whole are distributed irregularly in regard to their distance from the main dressing stations they serve. The same reason also helps to account for the differences in the habitations of casualty clearing stations. Some are in permanent buildings in towns or villages, some in huts far away from all other buildings; others in huts and tent-marquees, others in tent-marquees alone. The completely tented casualty clearing stations are usually found to be in the new parts of the line. As they settle down they acquire huts for operating theatres and administrative purposes, and if, later on, when the line moves forward, the sites that they occupy are likely to prove suitable for stationary hospitals, all the tents are replaced by huts.

THE FUNCTIONS OF A CASUALTY CLEARING STATION.

A casualty clearing station is in principle a mobile unit, since it must always keep within reasonable distance of

the main dressing stations; and therefore be prepared to move when these are moved, in conformity with any change in the tactical situation of the troops they serve. Primarily it is an evacuating unit, and only intended to act as a hospital so long as it is forced by circumstances to retain its patients, and it was probably in order to keep its status well in the foreground that not long after the war began the title "casualty clearing station" was substituted for the original term "clearing hospital." For a corresponding reason every casualty clearing station is provided with three lorries of sufficient size to transport at a moment's notice all the equipment that strictly speaking it is entitled to possess.

But however thoroughly casualty clearing stations may justify the suggestion of their title, they always go a good deal beyond it; for their functions and personnel have been adapted to existing circumstances by the D.G.M.S. in France. Hence they are no longer mere stations but real hospitals, despite the fact that some are only about six miles from the fighting line, and few lie further off than double that distance. The patients are nursed by trained women nurses; ordinary hospital beds are provided for the more serious cases; the operating theatres have usually four operating tables, are equipped with electric light, and the appliances familiar in the hospitals of large towns; and while some have x-ray annexes of their own, all have at their command the services of travelling x-ray outfits, and clinical laboratory work is done for them by the mobile laboratories which are commonly to be found in their neighbourhood.

When a casualty clearing station has been established for some little time, the chief differences between it and a base hospital are attributable to the diversity of duties that the casualty clearing station has to fulfil. In addition to acting as a true hospital for a short or long period, it must always be ready to operate on a very large number of patients, and to evacuate forthwith those that can safely be moved, and must also be able rapidly to prepare for immediate evacuation a very much larger number of slight cases. It must also be ready suddenly to receive and accommodate in one fashion or another an almost unlimited number of sick and wounded. Consequently, in addition to whatever accommodation in the way of actual beds it may possess, it must provide also:

1. Tents in which men lying on stretchers can be kept under cover, and receive what they require in the way of food, warmth, and surgical attention.

2. Accommodation for classifying the cases that arrive according to whether they must undergo operations under an anaesthetic, or merely require some such attention as the redressing of a wound or the replacing of a splint.

3. Accommodation for men who have received all the attentions they need, and are merely waiting to be loaded on the train.

4. Accommodation for the performance of minor surgery.

THE WORKING OF A CASUALTY CLEARING STATION.

There are considerable differences in the way different casualty clearing stations meet these needs, but in regard to definite operations the general practice is to provide sufficient accommodation and personnel for the performance of at least four operations simultaneously and continuously for an unlimited number of hours or days. Even when a battle is in progress, of the wounded men who arrive at the casualty clearing station at least 10 per cent. must visit the operating theatre before they can be sent to the base hospitals.

In regard to other matters the general procedure is usually as follows: As soon as a convoy arrives the patients are all off-loaded promptly so that the ambulance shall not be detained. They are carried into a distributing room, where, while a clerk takes down particulars of his army status, etc., a medical officer decides to what class of case each patient belongs, being guided in this matter partly by his condition, partly by what is stated on his field medical card.

Thus, for instance, A, who has an abdominal wound, is sent straight to the operation-theatre preparation room. So, too, is B, who has a wound of the head and is insensible. C, who has a wound of the thigh, is sent to the stretcher case dressing-room; but D, who has an apparently corresponding wound, is for some reason in a state of profound collapse, and is therefore sent to the observation ward. E has a perforating wound of the upper thorax,

and is sent to the chest ward; while F, who has a flesh wound of the shoulder, is sent to the walking case dressing-room.

When A arrives in the preparation room all his clothes are removed, and he is got ready for a laparotomy, which takes place as soon as a table in the theatre is free. B, in addition to other preparations, has his head shaved, and is sent to the theatre as soon as a surgeon and anaesthetist are ready for him. It may be decided that no craniotomy should be performed, at all events until the patient has reached a base hospital, but the case must be thoroughly examined before this conclusion is reached.

C's stretcher is placed on trestles and his wound carefully examined to see whether any operation is required; if so, he too is sent to the operation-theatre preparation room; otherwise his wound is redressed and an extension or other splint suitable for train travelling is applied. D, on his arrival in the observation ward, is put to bed and submitted to various antishock measures until his condition is sufficiently good for an elaborate treatment of his wound. E, on his arrival in the chest ward, is examined by a medical officer who specializes in internal medicine.

When F enters the walking-case room his bandages are taken off and the required treatment applied, unless his general condition and his field medical card clearly indicate that no further interference with the wound is likely to be desirable until he reaches a base hospital. From the dressing tent for walking cases F goes to the evacuation tent for walking cases, where he is given food and cigarettes and waits for the ambulance train; a train is usually available every day, and even oftener in times of activity; but, if there is any delay, F is given a stretcher bed and his wound is redressed in due course.

Meantime, into another evacuation tent men who belong to the various classes, A, B, C, D, E, and who have come down with the same or a previous convoy, are being brought on stretchers from the wards or other places where they have been prepared for evacuation. The standing regulation is to send on all cases to the base as soon as suitable transport is available, but any case at all likely to suffer by transport is detained as a matter of course; chest cases are never sent down until all danger of haemorrhage is presumed to have ceased, and abdominal cases are detained until they have so far recovered that they can be sent straight through to Great Britain without further treatment at the overseas base.

In any case the number of men detained is usually quite sufficient to afford the personnel plenty of ordinary hospital work between the arrival of convoys, and in order to secure time for its due performance, even when fighting is heavy in the part of the line served by the casualty clearing station and casualties are numerous, every casualty clearing station has a partner located at the same rail-head, and the two are alternately "open" and "closed" for the reception of patients. When times are quiet the commonest plan is for the casualty clearing stations concerned to open and close on alternate days. During active fighting a casualty clearing station usually declares itself "closed" when it has a given number of unevacuated patients on its hands; its partner then takes the next convoys. Should it happen that the partners are both "closed," the D.M.S. of the army concerned sends later convoys to the casualty clearing stations of some other area under his command.

Specialist Surgeons.

As a convoy does not represent a specific number of patients, and the number of convoys dispatched from any main dressing station in any twenty-four hours depends entirely upon the state of the fighting, the amount of work thrown upon a casualty clearing station varies greatly from time to time. Sometimes it resembles that of an ordinary hospital in a manufacturing town where accidents are frequent; sometimes that of a main dressing station of so elaborate a type as to be able to perform both aseptic and septic operations, and so large as to be able to deal with 1,000 or more patients a day. Its permanent staff consists of seven medical officers, but when the fighting is heavy it is reinforced by medical officers drawn from casualty clearing stations, field ambulances, or other medical units in other parts of the line. On its permanent staff are always at least two surgeons experienced in all classes of operative work, including abdominal surgery, and the reinforcements sent when times are active include other surgeons of the same type. The net result, therefore, is that by arranging in groups the total number of surgeons and anaesthetists available, the necessary operations can be performed until the stress is over.

Distribution of Patients.

When the convoys are not large and not arriving in rapid succession, the work of distribution is done by the orderly medical officer on duty; at other times it is usual to select a surgeon of wide experience for the work, since the duty of the "spotting officer" then becomes a task of great responsibility. He must be able, for instance, to gauge rapidly the general condition of a patient and the probable degree of seriousness of his wound. In addition to bearing in mind continually how long it is likely to be before an ambulance train arrives to clear the hospital, he

FIG. 19.—Trailer with one half of its equipment unloaded. The cupboard most to the spectator's left is for dressings, the next for instruments, the next contains two anaesthetic tables, and the cupboard most to the right has three compartments for splints—long splints, thigh, short splints, arm, and leg splints respectively. The shelves above the cupboards show the method of packing dressings, etc.

must keep a constant eye on the operation list. Should the latter be comparatively short or the stream of patients be falling off, his task becomes relatively easy, since he can mark for the preparation room any cases which seem at all serious. In the contrary case, he must decide whether the individual and general interests would best be consulted by sending the case down to the base forthwith, should an ambulance train be waiting or expected shortly to arrive, or by keeping him, even though it is not likely to be possible to perform the operation for many hours.

Consulting Surgeons.

The clinical work of the casualty clearing stations in each army is under the supervision of an officer who in peace times is a well-known consulting surgeon, and corresponding supervision is exercised in respect of medical conditions by a physician of analogous experience.

Before being evacuated from a casualty clearing station a note is added to the field medical card of every patient as to the treatment he has received, and if an operation has been performed, or he has been detained as an ordinary hospital patient, clinical notes concerning his case for the information of the medical officers at the base are sent on in an envelope attached to a button of his bed jacket.

Many casualty clearing stations also do a certain amount of work in attending to local sick—that is to say, to cases amongst labour parties and other troops in their neighbourhood which are not in charge of a medical officer or within the area of the work of a field ambulance. It is also the

rule for a casualty clearing station to detail a medical officer to afford medical attention to members of the civil population if a request to this effect is made by the local civil authority.

THE THEATRE TRAILER.

Though a casualty clearing station is a mobile unit, the transfer of so large an institution from one site to another takes a considerable time. In an advance it may be desirable to push an operating section forward at once. To meet this need the "theatre trailer" has been devised. It consists of a large pitch-pine framework, which can be clamped on to a trailer drawn by one of the lorries of the casualty clearing station. The lorry is loaded with stretchers, blankets, cooking and feeding requisites for a hundred serious surgical cases for two days, and carries also a hospital marquee and operating tent. The original idea for the trailer, as suggested by Colonel Cutlibert Wallace in September, 1916, was to fit it with shelves and pigeon-holes, as on a ship. After further study, however, it was seen that it would be better to make the cupboards and other fittings movable, providing for the careful packing of their contents so that they would not suffer on the road. Each cupboard runs on four wheels, and is fitted to hold and carry without

FIG. 20.—Interior of a hospital train: the majority of lying cases are evacuated by ambulance train.

damage dressings, instruments, bowls, and enamel ware, as well as the Bowlby outfit and the marmites in use in almost every casualty clearing station theatre. There are two cupboards for sterilized dressings, overalls and towels, sufficient for one day's operating, with two surgeons and four tables, dealing with 150 major operations. In addition, six complete sterilizing drums are carried, and in all sufficient dressings for 500 operations. Lotions, made up in quart bottles, are packed in a specially designed case fitted in one of the shelves. Boiled water and saline are taken in sterilized petrol tins. The instruments are packed in webbing straps stitched together and attached to the shelves. Three anaesthetic tables and folding stools are packed into two cases, which, when unpacked, can be used as surgeons' washing-up benches. The bottom shelf of each anaesthetic table contains nine compartments, each of which holds a two-pound bottle of chloroform or ether. Two other shelves contain the anaesthetic apparatus, masks, gauze, etc. Other cupboards contain primus stoves and their fuel, cleaning materials, a rack for splints, and a stand for the lotion copper cauldrons. The shelves fit one above the other, and can be built up in any order that may be desired to form dressers or small cupboards. The contents of one side lifted out of the trailer are shown in the illustration (Fig. 19). With the trailer and trolley are four R.A.M.C. orderlies, and there are two Army Service Drivers. These six men can pack the loaded furniture into the trailer in ten minutes. The main advantages of this trailer, the details of which have been worked out by Captain E. M. Cowell, R.A.M.C.,¹ and Lieutenant-Colonel G. H. Goddard, R.A.M.C., are that it ensures the careful transport of the delicate equipment of an operating theatre and provides operating room furniture ready for immediate use in all circumstances.

¹ A full account of the Wallace-Cowell trailer, with details of construction and stores, will be found in the *Journal of the Royal Army Medical Corps* for June, 1917.

AMBULANCE TRAINS AND HOSPITAL BARGES.

A patient may be sent down through the evacuating zone to the base either by ambulance train, by hospital barge, or by motor convoy; in the great majority of cases the first is the method employed.

AMBULANCE TRAINS.

Several types have been used since the war began. In the early days the predominant type was made up mainly of goods vans fitted with racks to support stretchers, and supplemented by straw-strewn vans for the more lightly wounded. These trains were effective so far as actual transport was concerned, and were easy to load and unload, since the doors were wide; but the carriages could not be lighted easily or kept warm, they afforded no conveniences for administrative work, and it was very difficult for the medical officers to attend to their patients once the train had started. Moreover, unless the vans were drawn from passenger trains, and this was comparatively rare, they were mounted on four wheels only, had very ineffective springs, and practically no brakes. They were gradually displaced by trains built up of ordinary passenger coaches supplemented by a saloon or

restaurant car for administrative purposes. The compartments were so arranged that they could each contain four stretcher cases lying at right angles to the line of travel. Most of the coaches thus used had six wheels, and were much better sprung and braked than goods vans. They were also much better lighted, and, as a rule, each vehicle had a firebox attached exteriorly, and thus had independent heating. On the other hand, loading and unloading was not easy, since the doors were narrow, and only rarely was it possible to arrange for intercommunication between all the carriages, so that some of

them could be visited only by walking along the foot-board or by stopping the train.

A few trains of this type are still in use, but the majority belong to a third type, which is built up partly of corridor car "coaches" for patients able to sit up, partly of specially constructed "ward" carriages (Fig. 20), intercommunicating cars with tiers of berths down each side and a passage way between them. These berths are open at the ends, and have both wire and ordinary mattresses and blankets and sheets, and the patients are habitually put to bed in them, unless for some reason, such as the existence of an injury to the spinal column, it is desired to avoid moving a patient off his stretcher. In such cases the stretcher is laid on the top of the bed. These tiers of beds are arranged parallel to the line of travel, and as there are six sets of tiers on either side and each consists of three berths, the normal accommodation of a travelling ward is thirty-six patients, while if occasion requires, it can be increased to forty by laying stretchers in the passage way between the tiers.

The usual plan is to place the carriages in the following order, working from the engine backwards: A carriage used as an isolation ward; a coach with its compartments arranged as sleeping quarters for the medical and nursing staff; a kitchen coach; four or five ward carriages; an administrative carriage, providing an office, a room for the performance of operations (Fig. 21), and a dispensary; four or five coaches for sitting-up patients; a carriage for

general cooking purposes; a coach to serve as sleeping quarters for the subordinate personnel; a van for stores; and a guard's van. About 400 patients is an average load for such a train.

The "ward" carriages have wide external as well as internal doors, so that they are easy to load and unload, and the train is electrically lighted and steam heated from end to end. The wide doors of communication between the carriages afford a vista of half a dozen carriages in succession, and the actual passage way extends from one end of the train to the other. All the ward carriages, moreover, are mounted on well-sprung eight-wheeled chassis, and a Westinghouse compressed air automatic brake operates from end to end of the train. The net result is that they are easy to work and run smoothly even over the much-used permanent ways of Northern France.

All the advantages of these trains are attained likewise in a fourth type, which is the latest to come into use. In it the accommodation for patients consists entirely of ward carriages, wherein as much provision for sitting-up patients as may be required is made by turning up the middle berths of the tiers, thus leaving the upper berth for a lying-down case, while the lower one forms a sofa for three or four sitting-up patients. In the third type of train the sitting accommodation in the coaches often proves to be in excess of the requirements, so that the fourth type represents economy in engine power and rolling-stock, since, whatever the proportion of lying-down cases to sitting-up cases, the whole of the accommodation can be utilized.

Ambulance trains so long as they are loaded are managed very much as if they were ordinary hospitals, but there is not usually very much dressing to do unless in a considerable proportion of the cases irrigation treatment is being applied. There are always, however, patients who require attention, and for the first hour or so, at any rate, after the train has been loaded the whole of the staff is kept busy. Once they have settled down the majority of patients sleep peacefully to the end of their journey, even those who are travelling in sitting-up coaches. They have left the battlefield behind them; they have had their wounds dressed, and all tension is at an end. This restfulness of an ambulance train, despite many physical reasons to the contrary, was noted long before the prevailing type of train came into use, and is one of the more curious psychological features of the war.

For an ambulance train of the second type the allowance of medical officers is usually three, but for the third and fourth types only two are generally required; in each case three or four sisters are carried in addition to nursing and general-duty orderlies, cooks, etc. Unless a journey is unusually long, the majority of the staff remains on duty during the time the train is loaded. As soon as the patients have been unloaded the whole train has to be cleaned, bed-linen changed, dirty linen dispatched to the wash, and fresh supplies of stores obtained, so that rest for an ambulance train staff does not come until the up-country journey has commenced.

The movements of the trains as a whole are regulated by a medical officer of the staff of the D.M.S. Lines of Communication. If a full load is not waiting at any single rail-head, several are visited in succession. Once loaded, the train travels at a rate of about twelve miles an hour to its destination at the base, which may be anything from

fifty to a hundred miles away. Information as to the hour of its probable arrival is telegraphed to an officer at its destination, who meets the train with a sufficient number of stretcher-bearers and motor ambulance cars to distribute the patients promptly among the various hospitals at this base.

HOSPITAL BARGES.

Evacuation by hospital barges is necessarily restricted to parts of the front traversed by navigable canals, and also by the fact that comparatively few casualty clearing stations lie sufficiently near canals for patients to be embarked without an intermediate journey in an ambulance car. This means of evacuation is slow, but is of use in dealing with patients for whom it is desired to secure absolute freedom from shaking. Barges, however, are not used solely for evacuating purposes; in certain parts of the line they can be taken close up to main dressing stations and advanced operating stations, and can then be used either to provide additional accommodation or practically as if they were travelling casualty clearing stations, chest cases and abdominal cases being placed straight on board after operation and taken down to a port, where they are evacuated to a home base by being loaded on a hospital ship.

The barges used are those familiar on Flemish canals (Fig. 22). When one end of the interior has been partitioned off into cabins for the staff, and the other into a kitchen, scullery, and quarters for the subordinate personnel, there remains ample room in the middle for thirty ordinary hospital beds arranged fifteen on each side with a passage between them. There is a space amidships into which patients are lowered from the deck above by means of a hand lift. This space can be used for the performance of operations if necessary. Except that its ceiling is low (about 10 ft.) and its diameter comparatively narrow (about 16 ft.), a barge ward looks very much like a hospital ward (Fig. 23).

All the barges are provided with a dynamo and gas engine; they can be lighted either by electricity or by removing one or more sections of the deck which forms

FIG. 21.—The operating theatre of an ambulance train.

the ceiling of the ward. They are drawn by a tug in charge of men accustomed to canal work. They are divided into flotillas of four, but more often than not they travel singly or in couples. Every barge carries two trained women nurses in addition to nursing orderlies, general orderlies, and cooks. Each barge also carries a medical officer, unless two barges or more are travelling together, and then one is sufficient for all of them. The average duration of a barge journey is from twenty-four to forty-eight hours. They travel only by daylight, and at the rate of about three miles an hour.

STATIONARY HOSPITALS.

At places along the railways traversing the evacuating zone there are medical units known as stationary hospitals. These in theory are 200-bed hospitals of comparatively simple equipment as compared with that of a general hospital. Their bedsteads, for instance, are folding iron "barrack bedsteads," and they are not supposed to have clinical laboratories or x-ray annexes. In France, however, nearly all stationary hospitals are capable of accommodating several times their regulation number of patients, and many in point of equipment and extent of accommodation do not differ from the large general hospitals in the

distributing zone, unless they are used to fulfil some special aim.

Such of these units as are in the evacuating zone do their work in direct association with main dressing stations, and since the dispatch of a patient to them does not necessarily entail his formal evacuation, they are almost to be regarded as annexes thereto and therefore as front-line units. The rest are used for the reception and treatment of cases of sickness and injury among troops on the lines of communication, and for cases which the medical officers in charge of ambulance trains may think it desirable to off-load at the earliest possible moment. Strictly speaking, a stationary hospital is not entitled to more than seven medical officers, but it is allotted a larger number if it accommodates more than its regulation number of patients, and is doing work which for its due performance requires an augmentation of the staff.

FIG. 22.—Hospital barge being towed.

CONTROL.

It is from general head quarters that the Director-General of Medical Services usually controls the whole of the medical work of the front through the Directors of Medical Services of the different armies, as also that of the evacuating zone and the distributing zone through the Director of Medical Services Lines of Communication.

The operations thus controlled include not only the disposition and maintenance of hospitals and other medical units, together with all the arrangements for the evacuation of patients from the front to the bases and from the bases to the United Kingdom, but also certain other important branches of work. These are the distribution of medical reinforcements, the co-ordination of action throughout the whole British force in regard to sanitation and the prevention of epidemic disease, and the work of weeding out from the armies men who, though still useful soldiers, are not capable of doing front-line work, many of whom must eventually be sent home to be discharged from the army.

At the same place are also held the periodic meetings of a council formed by the Director-General of Medical Services to assist him in the settlement of questions from time to time arising. It consists of eight members and is so constituted that the temporary and permanent elements of the medical service of the army, general and bacteriological hygiene, medical and surgical work at the front, the same work at the bases, and administration throughout the whole area, are all represented in equal proportions.

There is a second council of the same general kind, which includes the whole of the civilian consultant specialists holding temporary commissions in the army, as

well as the principal permanent officers on the staff of the Director-General of Medical Services. But this meets less often owing to the difficulty of withdrawing so many officers from their ordinary work simultaneously.

THE DISTRIBUTING ZONE.

The hospitals to which the patients are sent on their arrival in the distributing zone are known as general and stationary hospitals. The former are in theory much larger and more comprehensively equipped than the latter. In practice, however, there is in France often no difference even in point of size, and invariably both afford the same facilities for the best forms of medical and surgical work. That is to say, their ward equipment is of the same kind as in large civil hospitals in times of peace, they have all large and elaborate operating theatres and annexes, and bacteriological laboratories and x-ray annexes.

ORGANIZATION OF GENERAL AND STATIONARY HOSPITALS.

In point of size every stationary hospital can now accommodate at least 500 patients instead of the regulation 200, and every general hospital at least 1,040 instead of 520. The larger figures represent the number of beds kept at all times ready for the reception of patients. In time of pressure the accommodation can be increased by some 50 per cent. The clinical work is divided into a medical and a surgical division, each in charge of a specialist assisted by ward medical officers. To the

surgical division there are also attached specialists in operative surgery who vary in number according to the accommodation of the hospital.

The nursing is done by trained women, those appointed to each ward working under the supervision of a ward sister, who is subject in her turn to the hospital matron. There are also a certain number of orderlies trained in nursing duties, who assist and on occasion replace the women nurses, and of general duty orderlies who do all the rough work of the hospital. The male

FIG. 23.—Interior of a barge full of wounded.

personnel is under the control of a non-commissioned officer commonly called a wardmaster, who is subject in his turn to the sergeant-major of the hospital. Supplies of every kind are obtained by the quartermaster, who is responsible for their due preparation. He holds honorary rank as an officer in the Royal Army Medical Corps, and to attain this position he must not only possess tact and good manners, but must pass examinations in general education and technical and military subjects spread over so many years that most quartermasters are men who have entered the corps at a very early age.

The laboratory and x-ray rooms are in the charge of specialists, privates or non-commissioned officers who have received training in these duties being appointed to assist them. The institution as a whole does its work under the control of an officer of the rank of lieutenant-colonel or colonel, who in the larger hospitals has a registrar to assist him in the keeping of medical records. In times of pressure this officer commonly takes charge of a certain number of beds, and often also acts as company officer or adjutant, his work including disciplinary control of the more military side of the work of the unit.

A few hospitals occupy large buildings, such as casinos or hotels, but most of them now lie in camps outside the towns, of which they nominally form part. They are formed sometimes of huts alone, sometimes of huts and marquees. The marquees have boarded floors, stoves, and electric lighting and double roofs. In fine weather the whole of one side of a marquee can be removed, the patients being thus kept practically in the open air; the marquees can also be placed end to end, a continuous ward capable of holding perhaps a hundred beds being thus formed. The hospitals at bases are rarely moved, so that not only are the camps they form irreproachable in the matter of sanitation, but they are almost invariably attractive likewise in other ways, as there is much rivalry among the staffs of different hospitals, and neat paths, shrubs, and flower beds spring into existence with great rapidity.

But, although base hospitals are well equipped and managed on identical principles, they are differentiated to some extent by the character of their work. At each base, for instance, one hospital deals solely with infectious diseases, while the rest, though prepared to take cases of all kinds, habitually specialize in the treatment of some particular class of injury or disease—for example, skin disorders, ophthalmic troubles, jaw injuries, nerve complaints, head cases, and fractures of the lower extremities. There are also some base hospitals which, owing to their distance from evacuation points, deal mainly with comparatively light cases.

At all base hospitals the time for which serious cases may be retained is not limited, but the general rule is to transfer to Great Britain any cases which are deemed fit for transport and are not likely to be fit for active service again in less than three weeks. Patients who complete their treatment in the base hospitals are sent on their discharge to convalescent dépôts, where they remain for a varying number of days, and thereafter, if considered fit once more for the front, are sent to the dépôts of the regiment or corps to which they belong. In the contrary case they are marked as base details and are kept under medical observation in barracks and employed on duties of various kinds.

BASE MEDICAL STORE DÉPÔTS.

Other medical establishments at the base are dépôts of base medical stores (Fig. 24), whence all the up-country dépôts, as well as the local hospitals and ambulance trains, draw their supplies, and the base hygiene laboratories, whose main work is to test the purity of the food supplies of the troops. There is also at one base a large bacteriological laboratory devoted solely to research work, and much work of the same kind also goes on at the laboratories attached to the different hospitals. Sometimes the work

is done as an independent effort, sometimes in co-operation with the officers in charge of the mobile laboratories in the collecting zone, and as a means of testing how far the results there obtained are supported by observations made on patients who have reached a later stage of their illness or injury.

LABORATORIES: MEDICAL HISTORY.

The general control of all the laboratories and of their work in the investigation of the problems of epidemic disease is the special charge of an Adviser in Pathology to the Director-General of Medical Services. In addition two officers appointed by the Director-General represent the Medical Research Committee of Great Britain; their duty is to advise upon the systematic recording of clinical notes, so that the requisite data may be available for general medical statistics and for pension claims, and also to secure that the various new types of disease and injury seen in this war are made the subject of specific study from a clinical and a pathological point of view by selected officers. As comparatively few cases remain in the hospitals in France throughout their whole course, the work involves securing continuance of study of many of the cases on their arrival at home. The aim in view is to secure that all the data necessary for the formation hereafter of sound opinions as to the medical lessons of this war shall be duly forthcoming.

As in the various army areas, the clinical work at each base is supervised by consulting specialists in various branches of medicine and surgery, and dissemination of newly acquired knowledge is secured partly by memorandums issued from time to time by the Director-General of Medical Services, partly by meetings of medical societies established not only at the bases but in the collecting zone, and partly by publication of results in the medical press.

The base hospitals are also used

as dépôts for medical reinforcements, officers newly arrived from home being appointed to them, both in order that they may gain some experience of general routine, and also to enable the authorities to ascertain their physical and other aptitudes for work of various orders. The younger men are sent eventually to field ambulances and thence to regiments.

OVERSEAS CONTINGENTS.

All the great British dominions beyond the seas—India, Australia, New Zealand, Canada, and South Africa—have medical units in the field, though they are all worked on the same system as units which are strictly speaking Royal Army Medical Corps units, and they are all under the control of the Director-General of Medical Services. An account of one of these—the Canadian Army Medical Corps—written by Surgeon-General Fotheringham of that corps, will be published in an early issue. There have been one or two hospitals officered entirely by volunteers supplied by the faculties of certain universities in the United States of America, and some units working under the aegis of the British Red Cross Society. These also have been under the general control of the Director-General of the British Medical Service.

GENERAL ADMINISTRATION.

In most of the military hospitals in France the administrative work is done by permanent officers of the Royal Army Medical Corps, and the bulk of the executive

FIG. 24.—A store for an ambulance train.

work by temporary officers, who contract to serve for the year, but in most cases renew their contracts as a matter of course. For the first eighteen months or more all these officers were volunteers, but since all men under 41 are now liable for military service, a considerable proportion of those now arriving are selected by civilian Medical War Committees, in response to the demands of the War Office. In making the selection the committees have regard not only to the fitness of the individual for foreign service, but also to the question of his indispensability or otherwise from the point of view of the civil population among which he has been practising.

Intermediate between these two orders come a certain number of officers who have received commissions for the duration of the war, and who are usually doing special work of some kind, and a large number of Territorial and Special Reserve officers. The former are civilian medical practitioners who long before the war joined the volunteer body known as the Territorial Army as medical officers, and by taking part in annual exercises and in other ways acquired a general knowledge of military routine. The Territorial army was mobilized with the Regular army on the outbreak of war, and these Territorial officers, belonging as they did to regiments and field ambulances, were at first to be found almost exclusively in the front line formations, but many of them now hold administrative positions and posts as divisional medical officers of hospitals. The Special Reserve officers are usually young men who before the war undertook to serve in the Royal Army Medical Corps if required, and meantime went through a course of three months' training, receiving a small retaining fee in respect of each year their names were kept on the roll.

The nursing staff is drawn from an equally large number of sources. Some belong to the Regular army, others to the hospitals which in peace nominally form part of the Territorial army, others are nurses who in peace work independently, and many come from the overseas commonwealths.

The great variety in the components of the R.A.M.C. is a source of strength, since it ensures the inclusion of men of varied talents and representative of special knowledge of all branches of medicine and surgery. The whole corps is administered in a spirit which secures unity of effort among men of different mental constitution and previous experience, yet without trammelling individuality by the imposition of other than necessary rules and regulations. It is to this that is mainly to be attributed the successful working of the Royal Army Medical Corps in France, but material assistance has also been derived from the sympathy extended towards all medical affairs for the benefit of the troops by the Commander-in-Chief.

SEA TRANSPORT.

The motor convoys at the front are army units, but the ambulance cars by which patients are taken from the base hospitals for shipment to England are maintained by the British Red Cross Society, and at some bases are driven by women. As not all the bases are at a port, a short journey in an ambulance train sometimes intervenes between a patient's departure from a base hospital and his embarkation.

The embarkation medical officer is informed day by day as to how many patients are waiting shipment, and the proportion of lying to walking cases, and as soon as a ship is ready notifies each hospital concerned how many patients of each kind he can accommodate. Arrived at the quay-side, the ambulances are unloaded under the supervision of the embarkation medical officer, and as each case reaches the deck it is assigned a position on board according to its nature. Swing cots are used for the severer cases, since they can be approached from both sides, and to the less severe are assigned berths arranged in tiers. On long voyages walking cases are also given berths, but on short ones they are allowed to sit or stroll about as they please as soon as each man has been clad in a life-jacket. The next step generally is the serving of a meal and the distribution of cigarettes.

Meantime the lying-down cases are being treated as if they were still in a hospital on land, for every hospital ship has a staff of surgeons and nurses and all the equipment necessary for hospital work. All hospital ships have

previously been passenger vessels, and the necessary room for wards is provided partly by re-equipping the dining and other saloons for their new use, partly by clearing the lower decks of cabins. Lifts are provided for moving patients, and the vessels are painted white, with a green band painted from stem to stern with a red cross painted in the middle. At night there is a long row of red and green lights along the taffrail on both sides.

HOME HOSPITALS.

Arrived at the port of destination the patients are received by a disembarkation medical officer and his staff, who have been warned by wireless telegraphy of the number of patients on board, and have caused to be brought up to the quay-side the requisite number of hospital trains; these trains are then loaded rapidly by stretcher-bearer parties and dispatched to different parts of Great Britain.

The more serious cases are usually sent to hospitals in the neighbourhood of London or the great provincial towns. Some of the larger institutions are military hospitals which existed before the war, but the great majority have been specially created. Some of these, however, previously had a nominal existence as Territorial hospitals, it being part of the system of the Territorial Force that at each local centre the larger civil hospitals should undertake to open if required a military hospital officered by medical men selected from their own staffs. The officers thus selected were given commissions *à la suite* in the medical department of the Territorial Force. Apart from large military hospitals of this and other kinds, including some maintained by the British and other Red Cross societies, a considerable proportion of all civil hospitals now have arrangements for the reception of military patients who are treated by the civilian staffs attached to these hospitals.

All the larger hospitals have special departments for patients whose successful treatment involves knowledge of one or other of the special branches of medicine and surgery. There are also very numerous convalescent homes, and the orthopaedic hospitals described by Dr. Colin Mackenzie (BRITISH MEDICAL JOURNAL, May 26th, 1917, p. 669 et seq.). Finally, there are numbers of camps to which are sent men who it is expected will recover their fitness for active service when they have undergone remedial exercises of various kinds and a general physical training.

The duty of seeing that an adequate number of hospitals for military patients are maintained in Great Britain, as also that of providing the reinforcements and stores required for the medical work of the armies in France, the Balkans, Mesopotamia, India, East Africa, and elsewhere, appertains to the Director-General of Army Medical Services in London, a post filled since November, 1914, by Surgeon-General Sir Alfred Keogh. He had held the same office some years previously, and returned to it in order to allow the actual occupant of the post, Surgeon-General Sir Arthur Sloggett, to take up work which it was realized would be of weekly increasing importance and for which his talents and experience seemed, and have abundantly since proved, specially to fit him—namely, the control of the medical affairs of the British armies in France. It is on the arrangements of these armies that this description of the work of the Royal Army Medical Corps is chiefly based.

So far as the British people is concerned the work of the Royal Army Medical Corps has given the greatest satisfaction, and it is believed that after the war, when details become known to those capable of assessing its more scientific aspects, it will be acknowledged that the corps has taken full advantage of opportunity offered for advancing precise knowledge of medicine and surgery as well as of means of handling vast numbers of sick and wounded men.

M. MAGINOT, the French Colonial Minister, has issued a decree making infantile paralysis (acute anterior poliomyelitis) a notifiable disease throughout the French colonies, and prescribing isolation of the sick person for a period of thirty days, disinfection of all excreta, linen, and other objects used by the patient, and of the patient's room, and exclusion from school of brothers and sisters of the patient for a period of twenty-eight days.

British Medical Journal.

SATURDAY, AUGUST 25TH, 1917.

THE STAFF OF LIFE.

THE encouraging character of the statement made by the Prime Minister with regard to the food supply of the country during the coming autumn and winter must not lead to forgetfulness of his proviso. He said that "with reasonable economy" there is no chance that the population of these islands will be starved out. That such a statement should be universally, and rightly, regarded as encouraging is in itself proof that the situation has been and still is grave. When, early in the year, he uttered a warning, which to their eternal credit the housekeepers of the country took seriously to heart, our stocks of cereals were the lowest on record. Since then the situation has materially improved. A year ago the stocks of wheat in the country were 6,480,000 quarters, now they are 8,500,000 quarters, and the stocks of oats and barley are also higher than this time last year. The harvest in Great Britain promises well, and, as the acreage has been increased, the total produced will, with favourable weather for ripening and in-gathering, be larger than in 1915. The increased area under wheat, oats, barley, and potatoes, is about one million acres over 1916, and about three-quarters of a million over 1915. Owing to closer milling, and to the success of the economy campaign, there has been a saving equivalent to an addition of 70,000 quarters of wheat to the food supply of the country. So much for the credit side of the account. On the debit side the controlling fact is that the harvests of the world this year are not good. The harvests of France will be considerably below the average, because practically the whole of the men in the vigour of life have been withdrawn from agriculture, and this is the third harvest that has had to be raised and gathered without them. Therefore France must be a larger buyer in the markets of the world than ever before. The same statements are true of Italy. Economy in food, especially in cereals in this country, will have the effect not only of diminishing the demands on shipping urgently needed for other purposes, but will diminish the drain upon the reservoir of food which France, as well as Italy and ourselves, have got to draw upon in Canada, in the United States, and in the Argentine.

There will be great need for rigid economy in meat. Of the meat consumed in the five years before the war rather less than three-sevenths was imported. The American food controller anticipates a world meat famine owing to the great decrease in the number of meat-producing animals, and advises greater use of fish; but though it may be true that, as Mr. Hoover argues, every fish eaten helps to save meat, the economy will not be very great, for the quantity, including that imported (about one-seventh), was small, and its energy yield relatively low. The shortage of sugar is notorious, and is important, since on the average 13 per cent. of the energy yield of the nation's diet was obtained from it before the war. The reserve, the Prime Minister said, is now larger than in the early spring, but it is still low.

It is clear, therefore, that though the general position is better than it was, it still calls for careful

handling by the Government and judicious management in the household. The Government has profited by the mistakes of Germany to avoid legislative or administrative action which might tend to produce panic, and the housekeepers have shown what they can do when they try; they are asked to go on trying. Medical men, who will no doubt often be asked to advise, will be glad to have their attention directed to a pamphlet on *The National Food Supply in Peace and War*, by Mr. T. B. Wood, Professor of Agriculture at Cambridge, and a member of the Food (War) Committee of the Royal Society.¹ It is founded largely on the work of that committee, to which we have on several occasions called attention, but it is put together in a consecutive manner which makes it easy to grasp the problem and to apprehend the solution proposed. We counsel our readers to obtain a copy and keep it by them for reference, for we cannot here do more than indicate its general line of argument.

With the produce of all the world before him from which to choose, man has selected certain articles of food for his mainstay; but some are solid and others liquid, and if the value to him of the various articles is to be compared at a moment when circumstances compel him to produce and consume those yielding the highest energy value most economically, some common basis of comparison must be taken. It cannot be got by adding together the weights of milk and meat consumed, for instance. By common consent of all who have given serious attention to the subject, the basis must be an estimate of the energy yield of the various types of food; this is most conveniently expressed in terms of the calorie, a unit applicable to all energy-yielding substances whether converted in a steam engine, an internal combustion engine, or by the animal body. There are people who seem to take a pride in refusing to understand the object of taking this basis, arguing that the digestibility of the food is ignored. It is not ignored, but it is a different question which man has settled for himself through countless generations. Nobody proposes to feed a man on petrol, or a motor car on bread-and-butter.

Taking the total food consumption before the war and calculating the energy value of the food consumed by an "average man" before the war, it is found that it yielded in round numbers 4,000 calories as compared with the generally accepted standard of 3,400, an excess of 15 per cent. This is to be accounted for partly by loss in distribution, partly by waste in the household, and "possibly," Professor Wood says, "to a small extent by actual over-eating by some persons." Of waste in the household the largest item was fat from our fat meat, a form of waste which is one of the banes of the sanitary engineer. The waste of bread and other cereal products was extremely small, and is now probably so small as to be negligible. Of the total work-producing power contributed by the various kinds of food, the percentage yielded by cereals before the war was 34, by meat 18, by dairy produce (including margarine) 15, by sugar 13, by potatoes 10, and by fish, fruit, vegetables, and other minor articles 10. Of the 34 per cent. yielded by cereals 26 was consumed as wheaten bread, and the total from wheat flour was 30 per cent. These figures, taken as they stand, are enough to prove the outstanding importance of cereals, of bread in particular, but they are averages, and individual consumption varies enormously according to income, work, and convenience.

¹ Cambridge University Press, Cambridge, London and Edinburgh. To be obtained through any bookseller, price 6d.

Professor Wood estimates that the consumption of bread varies from 14 lb. a week by the agricultural labourer to 2 lb. by an unoccupied man of sedentary habits. Bread is the staple diet of the nation, especially of the classes engaged in manual work. Before the war all other cereals supplied less than one-eighth as much work-producing power as bread and flour, and of the total cereals consumed for human food only about one-fifth was home grown. One penny expended on bread provided nearly 900 calories before the war, now it provides about 400. Two-thirds of the calories required by an agricultural labourer were, and probably still are, supplied by bread. Potatoes probably came next, and were, and at the present moment probably are again, one of the cheapest of foods. Before the war a penny expended on potatoes provided 700 calories, on sugar 800, on milk 270, and on meat 150. Fresh vegetables and fruit are valuable rather for the vitamins they contain and their savour than for the energy they yield. Attempting broadly, very broadly, to summarize Professor Wood's advice to-day, it may be said to come to this—that we should regard the purpose of meat as we formerly regarded that of vegetables and fruit, and use it for its savour to make dishes palatable and stimulating to the appetite.

Before the war the average annual amount of corn available in the United Kingdom was 17 million tons, of which about 6½ million were home grown. About 5 million tons were used for human food, about half a million for seed, about 2 million for industries, chiefly brewing, and over 9 million tons for feeding animals; even of wheat, of which 4½ million tons were used for human food, animals consumed 2½ million tons, but this included the tail and damaged corn of the home crop and the "offals" of all the home and foreign wheat milled. Professor Wood maintains that quantities of grain so large as to make the situation secure might be diverted from animals to man. A certain number of horses are necessary for productive work, and the allowance for them is 3 million tons of concentrated foods, chiefly oats. To keep the supply of milk to the normal at least one million tons of concentrated food, chiefly oilcake and wheat offals, must be allotted to milch cows. The cow is an economical animal food producer, her consumption working out at 12 lb. of dry fodder for 1 lb. of dry human food. In any event, it would be essential to keep up the number of milking cows, but it is satisfactory to be assured that the cow is an economical converter, turning a diet consisting chiefly of grass, hay, and roots, which are not suitable for human food, into the milk indispensable for children. The pig is a good converter also, but he is fattened largely on meal made from grain which is now required for human food. This animal must be fed therefore in summer on grass and green foods, and in winter on roots, and must be killed for market early, omitting the finishing on grain in fattening for the market. The sheep is a fairly economical converter when the wool is taken into account, and there can be little to be said against mountain mutton economically, and very much to be said for it otherwise. Poultry are not extravagant producers, and may be economical if fed chiefly on scraps from house and garden, miller's "offal," and damaged corn. But there is nothing to be said for beef as normally produced in this country. A steer by the time he is prime and fat has consumed about 64 lb. of dry fodder and produces 1 lb. of dry human food. The fattening of steers for the market is, from every point of view, an extravagant process; if it were stopped after about three months, there would

be very little loss of weight and a great saving of fodder, especially of concentrated fodder.

Consideration as a whole of the data analysed by Professor Wood shows that the policy to be adopted must be based on certain general principles, and that of these the most important is to secure the maximum amount of food for human consumption; this entails prohibition of the use of potatoes and, with certain exceptions—samples not fit for human consumption, and supplies for certain classes of animals and industries—of cereals, for any other purpose than human food.

THE BRITISH MEDICAL SERVICES IN FRANCE.

We complete this week the publication of an article, the third of a series, giving a fuller and more complete account of the work being done by the Army Medical Service on the Western front, and the way in which the service has been organized there, than has hitherto been published. In the first of the articles (June 2nd) Surgeon-General Sir Anthony Bowlby and Colonel Cuthbert Wallace, two of the consulting surgeons with the British armies in France, described the developments which have taken place in British surgery at the front, the difficulties encountered in administration, the problems presented to surgeons and bacteriologists, and the manner in which they were tackled and more or less completely surmounted by administrative action, clinical discrimination, and laboratory inquiries. A striking illustration of the valuable results that may be obtained by a combined attack was afforded by gas gangrene. The clinical work of the surgeons, described by Colonel Wallace and Captains Frankau, Drummond, and Neligan, combined with the bacteriological and histological inquiries recorded by Captains McNea and Shaw Dunn, showed that the rapidity of the spread of gas gangrene into living voluntary muscle could be accounted for by the peculiar anatomical structure of muscular tissue, the sheaths enclosing the long individual fibres being so easily detachable as to form potential spaces into which toxic material could readily pass, causing necrosis of the fibres. The early selective invasion of single muscles suggested conservative treatment by the resection of such infected muscles in an early stage, a line of treatment fully justified by the results. In our issue of June 16th Surgeon-General Sir George Makins, who, like Sir Anthony Bowlby, was one of the first consulting surgeons appointed to the armies in France in 1914, described the development of British surgery in the hospitals on the lines of communication in France, the term "lines of communication" including in this instance the base hospitals on or near the French coast of the Channel. To this paper was appended the results of an important study by Captain Herbert Henry on anaerobes found in wounds and their mode of action in the tissues: the body of the paper itself contained an interesting and instructive account of what might be called combined clinical inquiry into the treatment of fractures, especially of the lower limb.

The third article of the series to which we are now referring is that on the Royal Army Medical Corps and its work, concluded this week. In it a consecutive account is given of the medical organization, from the battalion through the field ambulances, casualty clearing stations, ambulance train and barges, the hospitals at the bases in France, and the hospital ships that transport the wounded by sea, to the home hospitals. It is chiefly concerned with the organiza-

tion in France; incidentally it gives a fuller account than has yet been published of the work of battalion medical officers in the trenches, affording some notion of its onerous and dangerous nature, and of the ingenuity expended in preparing regimental aid posts in dug-outs, and in handling the wounded through the trenches.

The whole story is one of which the British medical profession may well be proud. It shows that rapidity of adaptation to new conditions which is the best evidence of robust mental activity. It reflects immense credit on the regular army medical service, a corps organized to administer the medical affairs of the small regular British army which existed at the outbreak of this war. The medical corps was as highly trained as every other branch of the "old contemptibles" described as the finest military force that ever took the field. After the magnificent resistance of that small army which ended with the offensive return at the Marne, the British nation, from England to Australia, understood the task before it, and the British medical service rose to the occasion by an appeal to the British medical profession which had an immediate and magnificent voluntary response. The military conditions were new, the surgical problems were new, and the medical officers were new. With our national habit of self-depreciation we may perhaps be disposed to overlook the splendid character of the response. The credit for the success achieved belongs in the first place to the regular army medical service itself, which under the guiding hand at home of Sir Alfred Keogh, and in France of Sir Arthur Sloggett and his lieutenants, Surgeon-General Macpherson, Sir T. Woodhouse, and Colonel Burchaell, not only showed great administrative ability along the old lines, but an adaptability to the new conditions, and a readiness to make use of the assistance the civil medical profession could give, which has perhaps never yet received adequate acknowledgement. We of the civilian section of the profession have equal reason to be proud of the extent and nature of the response made. The civilian profession at once gave of its best—clinical surgeons and physicians and laboratory workers. The results are to be seen by any one who has eyes to see, and there can be no doubt in any impartial mind of the astonishing efficiency of the British army medical service in France.

The criticisms of which a good deal has been heard recently, both in and out of Parliament, are not directed against any deficiency in the service: rather they assume a redundancy and assert that as good results could now be obtained by a smaller medical staff. This matter will no doubt be the chief object of the investigation to be undertaken by the medical committee which has been appointed to make an inquiry in France and in this country, and to advise whether the medical establishments of the British armies can be reduced without diminishing efficiency. If the committee, which will, we believe, very shortly go to France to begin its inquiry, comes to the conclusion that any such redundancy exists, it may be able to indicate some alterations to meet what is now a primary need—the adjustment of military demands to the conditions produced by the depletion of doctors on the civil side.

ARMY RECRUITING AND CLASSIFICATION.

It was officially announced during the week that Sir A. C. Geddes, who received the K.C.B. a few days ago shortly after relinquishing his rank as Brigadier-General, had been appointed Minister of National Service in succession to Mr. Neville Chamberlain. The expectation is that the responsibility for army recruiting and for the classification

of recruits will—subject to one proviso—be transferred from the War Office to the National Service Department, and that the medical tribunals which deal with appeals will be constituted of civilian doctors, it being understood that those who have received temporary commissions since the war began will remain eligible, on condition that (to use Lord Derby's figure of speech) they give up khaki for black coats—that is, they will be eligible as civilian doctors. The proviso touches the special boards of appeal on questions of health in cases in which there is any conflict of opinion. The question whether these boards should be continued and, if so, with what powers, or whether they should be replaced by some similar bodies, does not seem yet to be settled. The probability is that the present boards will be continued with perhaps enlarged powers, but whether these appeal boards should be related to the National Service Department does not seem to be yet determined, and an effort, it is stated, is being made to place them under the jurisdiction of the Local Government Board, though, so far as we can learn, no valid reason has been given for the suggested attribution. The general impression is that under the new arrangement the National Service Department will abolish the elaborate classification of recruits into numerous categories, and that there will be a reversion to the original plan under which medical boards were required to classify recruits only into three categories—namely, those fit for general service abroad, those fit for service at home, and those unfit for any service in connexion with the army. In the first there will be placed those men who are sound in health, that is, fit to be in the fighting forces, after training; and in the second, those who, owing to some physical defect or organic weakness, are not fit to join a fighting unit but are capable of ancillary service for the army. With these may be included some men such as cobblers and others skilled in trades necessary for the equipment of the armies in the field. Our Parliamentary Correspondent gives this information with all reserve, for the National Service Department has had little time for considering the problems turned over to it. It is believed that the intention of this authority is to aim at simplicity in its arrangements, even though this may prevent the taking up of some capable men who would, under the scheme now brought to an end, have been brought in. The net result seems to be that in order to avoid friction there will be some sacrifice of potential recruits. Whether this is to be regarded as a satisfactory result in the interests of the nation is a matter upon which we prefer not to express an opinion, but there is no doubt that it will simplify the task of the medical boards.

IMPROVED PUBLIC-HOUSES.

At a meeting of the True Temperance Association on July 25th, 1916, a committee was appointed to draft a scheme for the improvement of public-houses in the interests of real temperance, and this Committee, which consisted of the Earl of Plymouth (chairman), Lord Lamington, Sir William Bennett, Mr. Gordon Selfridge, and Mr. Ernest Williams, has now issued a very interesting report. The Committee proceeded on the principle that temperance, apart from State action against disorderly drunkenness, is an individual matter, that it is not for the State to prescribe what a man shall eat or drink, or how he shall amuse himself; but that individuals and organizations can help by example and precept to raise the standard of temperance, and conditions can be created otherwise than by restriction, which will encourage temperance. One very obvious suggestion is the improvement of the public-house so that it shall be in truth a place where men and women may eat and drink in reasonable comfort, instead of, as is so often the case, a mere conduit for the delivery of alcoholic beverages. Before the war a certain amount had been done in this direction, notably by an association which controls a number of licensed houses

mostly in the south of England, and by certain affiliated county trusts. The policy of this association has been to acquire fully licensed houses, and to put in managers whose emoluments do not vary with the amount of alcoholic drink sold; the superiority of these houses in point of comfort to the average public-house or temperance hotel is indisputable. Since the war the State itself, acting through the Central Control Board (Liquor Traffic), has conducted experiments on these lines, notably in Carlisle, which have been reported from time to time in our columns. In practice it has been found that experiments similar to those of the association mentioned have not always proved financially successful. Indeed, in some districts what has happened has been analogous with the old economic principle known as Gresham's law—namely, that bad money drives good money out of circulation—the competition of the “bad” public-houses ruining the “good” ones. One reason is that, while the public will consent to drink beer wedged tightly together in a bar, they will not consent to consume tea in the same way, and, as Dr. R. Murray Leslie has pointed out, one of the absurdities of our present licensing laws is that it is not the accommodation of a public-house which is licensed but the amount of floor space. In practice, although the commercial profit on the sale of a cup of tea is larger than on the sale of a glass of beer, the final profit earned by a public-house that does no trade in tea may be much greater than that of one which lays itself out to meet the wishes of customers who are either abstainers or who at the moment want something non-alcoholic. The Committee is alive to these difficulties, and proposes, *inter alia*, that “improved public-houses” should have a substantial rebate upon the licence duty and should not be subjected to contribution to the fund which has been established for compensating the owners of houses closed under the existing reduction scheme. One of the practical difficulties of the proposals is the impossibility of framing a satisfactory definition of what constitutes improvement, a difficulty which is not removed by the rather vague suggestion that it “only means the exercise of a little more imagination and the taking of a little more trouble by the authority.” Upon this the Board of the Licensed Victuallers' Central Protection Society (which, if pessimistic, is by no means unfavourable to the general scheme) not inaptly remarks that it is “precisely in that quality (imagination) that the authorities with whom the licensed trade at present come in contact are conspicuously deficient.” The Committee has submitted its scheme to various representatives of interests involved, and it has met with general approval. We have no space to comment upon the specific measures advocated, but the general idea is sound, and it is to be hoped that the subject will in due course be brought before Parliament.

ANAPHYLACTIC AND PSEUDO-ANAPHYLACTIC SKIN REACTIONS.

In the course of a detailed discussion of the mechanism and clinical significance of anaphylactic and pseudo-anaphylactic skin reactions Kolmer¹ points out that Edward Jenner in 1798 first described this phenomenon as the result of applying variolous matter to the skin of a woman who had had cow-pox thirty-one years previously, and that he stated that “the disposition to sudden cuticular inflammation” following the application of small-pox or cow-pox matter “may be effected by the small-pox or cow-pox,” and that its appearance justified the conclusion that the person had had one of these diseases, and now was not susceptible to either. This was forgotten until Arthur in 1903 rediscovered the local anaphylactic reaction, though previously Koch had noticed, without appreciating its significance, the local reaction following the injection of tuberculin into tuberculous guinea-pigs. There are three

forms of skin reactions: (1) The true or specific anaphylactic reaction due to the interaction in the skin of the specific protein antigen and specific antibody; (2) the pseudo or non-specific protein reaction due to the interaction in the skin of general protein substances, such as those in ascitic fluid, agar, and broth, and the non-specific proteolytic ferments contained in the blood serum, leucocytes, and fixed cells of the tissues; (3) traumatic, due to mechanical injury, to the irritant properties of preservatives, such as carbolic acid or tricesol, contained in the injected material, or to preformed bacterial poisons (as in the case of diphtheria toxin used in the Schick test). Of the various methods of obtaining the skin reaction the intradermic is the most delicate means of eliciting a local anaphylactic response, but is also the most likely to induce the non-specific and traumatic reactions. A local skin reaction may be an expression of an anaphylactic state to a certain protein, but as yet there are not sufficient data to prove that the mechanism of the local or skin reaction is identical with that of the general and fatal reaction following intravenous injection. After discussing the rival humoral and cellular theories of the mechanism of hypersensitiveness Kolmer concludes in favour of the latter, namely, that a diffusible protein poison forms mainly on or in the cells. Certain drugs increase the non-specific skin reaction: thus normal persons under the influence of iodides may give a positive result to the intradermic injection of luetin; this it effects by facilitating the activity of non-specific proteolysins and the production of protein poison, through the removal of antiferment. While a specific anaphylactic skin reaction is a delicate index of hypersensitiveness to a certain foreign protein, and its severity is an index of the degree of hypersensitiveness, the main clinical significance of the non-specific protein skin reaction is the likelihood of mistaking it for a true anaphylactic reaction.

THE SURGERY OF THE ORGANS OF LOCOMOTION.

The first number of the new Italian journal¹ devoted to this subject appropriately begins with a dedication to the late Professor Alexander Codivilla, of the Rizzoli Institute of Bologna, and the first article is by his distinguished successor, Professor V. Putti, who edits the journal. In this paper, which deals with surgical mobilization of ankylosis of the knee (arthroplasty), Professor Putti discusses the indications for operation and the methods of intervention, and favours detachment of the tibial tubercle and elongation of the tendon of the quadriceps rather than division of the patella or its ligament. He considers that a portion of the fascia lata of the thigh, excised through a prolongation of the incision over the joint, forms the best covering for the bone ends, and that it is best, when possible, to cover both bone surfaces with fascia. He thinks it has been proved that “human fascia interposed between the articular bone surfaces, lives, and goes on to a cartilaginous metamorphosis, which tends to renew the normal conditions of articular morphology.” The after-treatment by active and passive movements and simultaneous application of heat by means of electric thermophoresis is, he says, of the greatest importance. Professor Putti gives full details of six cases; three were examples of ordinary pyogenic origin and three the result of gonococcal arthritis. In one of the first three the operation was a failure owing to suppuration. This failure he attributes to a too early intervention. In the remaining five cases there was movement of 50 degrees to 90 degrees range eight to thirty-six months after operation. These results must be considered very good. The article is very well and freely illustrated and is worth perusal. Dr. Serra's article on free transplantation of bone in the

¹ J. A. Kolmer, *Johns Hopkins Hosp. Bull.*, Baltimore, 1917, xxviii, pp. 163-173.

¹ *La Chirurgia degli Organi di Movimento*. Direttore: Dott. V. Putti, Professore straordinario di Ortopedia nella R. Università di Bologna; Direttore dell' Istituto Ortopedico Rizzoli. Bologna: L. Cappelli, Editore. Vol. i, Fasc. i, p. 153.

human subject is also of considerable interest, as it affords conclusive evidence of union of the graft with the host, without gross absorption of the former. Other articles are by G. Vanghetti on plastic amputation stumps, and by F. Delitala on the normal and pathological anatomy of the foot with particular reference to traumatic lesions. We cordially welcome this "war baby" among medical journals, and wish our Italian brethren all success in the speciality in which they have already achieved much.

DICHLORAMINE-T FOR NOSE AND WOUNDS.

IN a paper published in the JOURNAL of June 30th last (p. 865) Drs. Dakin and Dunham described experiments with oily solutions of dichloramine-T (toluene-para-sulphodichloramine), and recommended its use in particular for the disinfection of the nasopharynx in carriers. Dichloramine-T though very sparingly soluble in paraffin oil, is quite readily dissolved in eucalyptol, and the resulting solution can then be diluted with paraffin. In this way a bland oily solution suitable for application to the throat, and containing 2 per cent. of dichloramine can be obtained. They directed that the nose should first be cleansed with salt solution or with 0.25 per cent. aqueous chloramine-T solution, either by spraying several times, using the handkerchief between applications, or by irrigation. The oily solution is not in itself as efficient in removing inspissated secretion as watery solutions. They advise, also, the use of chloramine-T solution as thoroughly as possible as a gargle. When the augmentation of nasal secretion produced by the solution of salt or chloramine-T has subsided, the oily solution of dichloramine-T is applied with an oil atomizer, an endeavour being made to reach all parts with an abundant supply of the oil. Introduced in this way the oil cannot be expected to continue active for more than two hours, so that for intensive treatment it should be renewed at the end of that time. In any case it is considered important to repeat spraying with the oil often enough to ensure at least four oil treatments daily at about equal intervals of time. Messrs. Boots, Nottingham, have sent us a specimen of an outfit for carrying out this treatment. It consists of three bottles, one containing dichloramine-T (forty-four grains), another chlorinated eucalyptol (one fluid ounce), and the third, chlorinated paraffin (four fluid ounces). The dichloramine-T is dissolved in the chlorinated eucalyptol without heating and the resulting solution poured into the chlorinated paraffin and well mixed. The outfit also includes a "cloudizer," which gives a fine spray; ten to twenty vigorous presses of the bulb should be used for each nostril. The price of the outfit is 7s. 6d. In a note to their paper Dakin and Dunham stated that Professor Sweet and Dr. Lee, of Philadelphia, had undertaken to test the use of a similar oily mixture containing 5 per cent. of dichloramine-T as a surgical dressing for infected wounds, and we publish this week a note from Professor Sweet, who is serving as a captain of the Medical Reserve Corps, United States Army, in a British hospital in France, upon the results of the treatment of wounds there with the oily solution, for the preparation of which he gives directions. As will be seen, this preliminary report is very favourable to the method, on the ground that it saves the pain of wound dressing, and economizes both dressing materials and the time of the surgeon, while the progress of the wounds is most satisfactory.

THE BACTERIOLOGY AND TREATMENT OF PYORRHOEA ALVEOLARIS.

PROFESSOR W. KOLLE has published¹ recently the results of observations on pyorrhoea alveolaris. In all the ninety cases examined he found a spirochaete differing in several respects from the spirochaetes often found in the healthy

mouth. It measured 10 to 12 μ , had four to seven convolutions and definitely pointed ends, and could be found in great quantities and practically in a pure culture by introducing a platinum needle into the deep pockets between the alveolar margin and the gum after the pus in these pockets had been squeezed out and wiped away. Professor Kolle believes that this spirochaete, which stained deeply with gentian violet but only faintly with Giemsa, plays the principal part in pyorrhoea, and he sees confirmation of this opinion in the strikingly beneficial effect of neo-salvarsan on the disease. A single intravenous injection of 0.1 gram was sufficient to effect marked improvement, and in many cases two injections, each of 0.3 gram, cured the disease within ten days. Some of these cases had been refractory to various forms of local treatment. As many as three to five injections were required in severe chronic cases. This spirochaete, to which Professor Kolle has given the name *Spirochaeta pyorrhoeica*, was found in decreasing numbers as the injections were repeated and the inflammation subsided; and it was also noted that recovery was hastened by the local application of neo-salvarsan.

SPIROCHAETES IN TYPHUS FEVER.

IT is announced in a Renter's message from Tokio that Professor Kenzo Futaki recently demonstrated at the St. Luke's International Hospital the presence of a spirochaete in the kidneys of seven fatal cases of typhus fever. He also stated that he had succeeded in infecting a number of monkeys and guinea-pigs with the spirochaete taken from typhus fever patients and had found it again in these animals. About six months ago (February 17th, 1917, p. 230) we noted that Professor Futaki and his assistants had discovered a new spirochaete which they believed to be the cause of rat-bite fever in Japan, and that these observations had been confirmed by other Japanese observers. Professor Futaki's claim to have found a specific spirochaete in typhus fever is interesting, but confirmation must be awaited, for organisms believed to be spirochaetes have been found in the blood and organs of man and inoculated animals on several occasions during the last ten years. It has to be remembered that bodies resembling spirochaetes can be seen by dark-ground illumination in normal blood. It is not stated that Professor Futaki has been able to cultivate the spirochaete he has found in typhus fever, and it may be assumed that he has used blood from patients for the inoculation of animals. This, of course, is a very different matter, for the blood would doubtless contain the infective agents whatever its nature. In this connexion it may be remembered that last November Hort showed before the Royal Microscopical Society photographs of a filterable virus, the injection of which produces the same clinical picture in monkeys as the fresh unfiltered typhus blood from human patients. His observations have not yet been published in full, but will, we believe, appear before long.

AS OTHERS SEE US.

OUR readers are familiar with the views of pessimists who regard the medical profession as helpless in its dealings with the Government and lay organizations. Those, however, who have closest relations with public men and Government departments know how far this view is from being generally held in such quarters. There is, indeed, a tendency among persons disposed to criticize the profession to overestimate the degree of unity it enjoys, and a strong belief that it is not only willing, but well able, to look after its own interests. Never a week passes but the diligent reader of certain periodical publications could find evidence of these views. As an example, we may take an article published in a recent issue of *Municipal Engineering and the Sanitary Record*. After commenting on the scheme for a Ministry of Health drafted by the Association, our contemporary goes on to say: "The recommendations,

¹ Med. Klin., January 21st, 1917.

whilst possessing a certain amount of originality, show, we think it will be generally concluded, that the British Medical Association has been too much concerned in promoting their own interests and in overlooking the fact that the ratepayer will not readily surrender his inalienable right to exercise reasonable control over the expenditure of the rates. They also show that the medical profession—close corporation as it may be—is not only a very powerful body but one of the strongest 'trade unions' in the country. As a consequence of their unity of purpose and of organization they are enabled to wield, not only at the Local Government Board and in Parliament, but in the country, a power which no other professional body of men can approach." Every organization must expect to be accused of self-seeking, but it is safe to say that in the clash of interests only bodies which are well organized and assertive are likely to receive adequate attention. We have not observed that anything in these days is gained by a policy of self-effacement, and experience has shown that, in spite of the power attributed to it in the paragraph we have quoted, the medical profession has often had to put up with very shabby treatment from the powers that be. The extract may show members who are inclined to talk of the political helplessness of the Association that their view is not shared by many of those outsiders who are supposed to see most of the game.

"MUSTARD GAS."

THE newspapers have recently contained a number of references to what is believed to be a new kind of poisonous gas used by the Germans. It seems to possess properties similar to those of the lacrymatory gas already well known, but of an aggravated kind; owing to its irritating qualities and its smell it has been given the name of "mustard gas." It is sent over in gas shells and is colourless. When diluted it produces smarting of the eyes, irritation of the nostrils, and so much dryness of the pharynx as to cause pain on swallowing and nausea. It is said to have a distinct smell and taste of mustard. When more concentrated its effect is very marked; it produces acute conjunctivitis with considerable swelling of the eyelids, inflammation of the nostrils, injection of the pharynx, vomiting, diarrhoea, and respiratory trouble suggesting bronchitis. In some cases the skin is actually blistered, and we have heard of one severe case in which the gas caused blistering on the abdomen, scrotum, and thighs, although the man was fully clothed. He was in a dug-out, and there may have been some unusual concentration of the gas on that account.

WORKMEN'S COMPENSATION: WAR ADDITION.

THE Workmen's Compensation (War Addition) Bill has been passed, and will come into operation as from September 1st next. The Act will apply for the duration of the war and for six months thereafter. Under it any person liable to pay compensation will be required to contribute an additional sum equal to one-fourth of the amount of his present liability. This is a serious matter, and employers should satisfy themselves that they are properly covered with their respective insurance companies. We understand that, so far as domestic servants (indoor and outdoor) are concerned, insurance companies propose to charge no additional premium, but as regards other employees, it is proposed to charge an additional premium of 10 per cent. This payment will accrue as from September 1st, but, as a matter of convenience, it will not be payable until the next premium falls due. So far as those who are insured through the Medical Insurance Agency are concerned, they will be notified that no additional premium will be charged for indoor or outdoor domestic servants, while any policy-holders liable for employees other than domestic servants will be required to fill up a form which will be sent to them notifying that they are prepared to pay the additional premium of 10 per cent. when the policy is renewable, and by the completion

of this form they will be automatically covered against the additional liability. Persons not already insured can obtain full information on application to the Agent and Secretary, Medical Insurance Agency, care of British Medical Association, 429, Strand, W.C.

We are asked to state that no election of direct representatives on the General Medical Council will be held in the present year, the provisions of the Parliamentary and Local Elections Act, 1917, having been extended by an Order in Council to the election of members of the General Medical Council by registered practitioners resident in the United Kingdom. The effect is to extend the term of office of the existing direct representatives until December 31st, 1918.

By the death on August 4th without issue of his second son the baronetcy conferred on Sir George Burrows in 1874 becomes extinct. Sir George Burrows, who was physician-in-ordinary to Queen Victoria, was a cousin of Sir Charles Hastings, founder of the British Medical Association, and married the daughter of John Abernethy. He was the first to hold the office of assistant physician to St. Bartholomew's Hospital, to which he afterwards became physician. He was president of the British Medical Association in 1862, when it held its first annual meeting in London.

Medical Notes in Parliament.

Medical Examination of Recruits.—In the House of Commons, on the motion for the adjournment, a large number of questions were raised, among which were some regarding the medical examination of recruits. One member read out a circular letter issued by the D.D.M.S. of the Scottish Command in the following terms:

There are very distinct indications that many medical officers, and more especially those who are serving in hospitals, do not realize the great essential duty of the military medical service to co-operate in maintaining the fighting efficiency of the armies in the field. The efficiency of the whole medical work in hospitals, from the military point of view and from the point of view of national safety at the present crisis, can well be judged by the numbers of men who are returned after treatment to the fighting lines, or to the training from which they came, within the shortest period of time.

While it is natural, and perhaps inevitable, that medical men should desire to have charge, and to treat from a scientific point of view difficult and "interesting" cases, and while from the ethical and political standpoint the utmost skill and care must be claimed for these cases, nevertheless it must be borne in mind intelligently by all that from this field of labour rifles are not most speedily returned to support or to be trained to support their comrades overseas.

It is by the earliest possible return of such cases that the medical service can gain the confidence and approval of the commanders in the field or at home, and can best further the interests of the army and of the nation at war.

On this point Mr. Macpherson, in his reply, said that it was clear that one of the first duties of medical officers in the army was to get an officer or soldier completely cured as quickly as possible in order that he might once again take his place in the fighting forces of the Crown. There was a dearth, not only of officers, but of men, and the service of those who had had experience were required as soon as possible. He was quite certain that no circular had been issued by the Director-General or anybody else designed to send men back into the ranks before they were completely cured.

Unregistered Dentists.—Mr. Raffan asked whether the Prime Minister had received a memorial, signed by nearly 200 members of Parliament, asking whether the Departmental Committee on unregistered practising of dentistry should be reconstructed so as to include representatives of unregistered practitioners and also a larger representation of members of Parliament. Mr. Bonar Law said the answer to the first part of the question was in the affirmative. As regards the second part it was hoped that it might be possible to take action in the direction suggested, but no definite promise could be made at the present time.

Parliament adjourned on August 21st until October 16th,

THE WAR.

RETURNED CANADIAN SOLDIERS.

A COMMITTEE, under the chairmanship of Sir Herbert Ames, M.P., was appointed by the Canadian Parliament some months ago to inquire into problems connected with the returned soldier. A number of sittings have been held in various places in the Dominion, and a great deal of evidence has been taken. The Committee has made the following recommendations:

(a) That both Federal and Provincial authorities take up without delay effective measures to prevent the spread of tuberculosis.

(b) That those soldiers who are hopelessly insane should be cared for at the expense of the Federal Government in provincial institutions under the same conditions as fellow citizens similarly afflicted.

(c) That returned soldiers who are suffering from venereal diseases should be quarantined at the port of arrival in Canada until cured.

(d) That orthopaedic institutions be provided at centres throughout Canada in addition to the one located at Toronto.

(e) That a sufficient number of returned men be induced to learn and follow the occupation of manufacturers of artificial limbs and that their services be utilized to supply limbs to soldiers free of cost and renewals and repairs at the cost of the State during the lifetime of the soldiers.

(f) That returned men who have been undergoing convalescent treatment and have partially completed courses of vocational training be allowed to continue such courses for a period of two months after their discharge as medically fit if, in the opinion of the vocational training officer of the district, it is in the interest of the State and of themselves that they should do so.

It is suggested also that the Dominion and Provincial authorities should co-operate in efforts to secure employment for returned soldiers, the responsibility for finding employment for such men to rest with the Dominion Government, with such co-operation as the provinces are willing or able to give. In the case of civil servants, it is advised that the time spent with the Canadian Expeditionary Force should be regarded as absence with leave, and their grade and standing in the public service determined accordingly. The Committee is divided in its view as to the control of the agencies which deal with the home-coming men. The majority, however, including the chairman, are in favour of relegating this matter to a special department of the Government; others consider the matter should be placed in the hands of the Militia Department.

HONOURS.

A SUPPLEMENT to the *London Gazette* issued on August 16th contains a long list of awards for conspicuous gallantry and devotion to duty in the field. The following awards have been granted to medical officers:

Bar to Distinguished Service Order.

Captain Eric Dalrymple Gairdner, D.S.O., M.B., R.A.M.C.

He went forward under very heavy fire to attend to a wounded non-commissioned officer, and was himself shot down. He has consistently displayed high courage and devotion to duty, and his example has been an inspiration to all ranks. (D.S.O. gazetted June 3rd, 1916.)

Distinguished Service Order.

Lieut.-Colonel (Temporary Colonel) Donald Johnstone McGavin, New Zealand Medical Corps.

While acting as A.D.M.S. to his division the successful evacuation of the wounded during our heavy offensive was due to the thoroughness of his preparations and his personal attention to the smallest details. He went into the advanced area at great personal risk to encourage the stretcher-bearers and superintend the removal of casualties, setting a splendid example to all ranks.

Temporary Captain (acting Lieut.-Colonel) Charles Derwent Pye-Smith, M.C., R.A.M.C.

When in charge of an advanced dressing station his sergeant-major and the whole of his staff were killed. He reorganized the work with the assistance of a lance-corporal, and, in consequence of his energy and presence of mind, the work was not delayed. He led his bearers continually into the front line, rescuing wounded under heavy shell fire, and working with great heroism for sixty hours, setting a splendid example to all.

Bar to Military Cross.

Captain Samuel Russell Foster, M.C., M.B., R.A.M.C.

He showed the greatest skill and fearlessness in leading his stretcher-bearers through a severe enemy barrage to evacuate wounded from our front line. His work has always been marked by utter disregard of danger, and his fine example has communicated itself to his men. (M.C. gazetted November 18th, 1915.)

Captain Frank Grahame Lescher, M.C., R.A.M.C. (S.R.).

He showed the greatest skill and fearlessness by leading his bearer parties and establishing forward collecting posts, under heavy hostile shell fire. He worked ceaselessly for three days, by his personal example and devotion inspiring his men with courage under very difficult conditions. (M.C. gazetted October 20th, 1916.)

Temporary Captain David Hamilton Hadden, M.C., M.B., R.A.M.C.

Under extremely adverse weather conditions he worked without rest for three nights and two days attending wounded. Throughout he showed the utmost indifference to heavy shell and machine gun fire. (M.C. gazetted January 1st, 1917.)

Military Cross.

Captain William Aitken, New Zealand Medical Corps.

He repeatedly took his bearers through heavy hostile barrage, clearing the aid posts and searching shell-holes for wounded. His gallantry and coolness under fire was of the highest order and a splendid example to his men.

Captain John Cook, R.A.M.C.

He went out under heavy shell fire, attending to the wounded, and carrying them to cover, and setting a fine example of fearlessness and devotion.

Captain Alexander Cosgrave Court, M.B., R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty in establishing an advanced aid post and personally attending to all the wounded under heavy fire. Though wounded in the hand, he carried on, saving many lives and showing great courage and initiative on this as on all other occasions.

Captain James Garfield Crawford, New Zealand Medical Corps.

He repeatedly took his bearers through heavy barrage, bringing back many wounded who were lying exposed to the enemy's fire. His coolness and fearlessness under heavy fire was a striking example to his men, and his energy was the direct cause of many lives being saved.

Captain Harry Edmund Creswell, R.A.M.C. (S.R.).

When casualties were very heavy he worked single-handed for thirty-six hours without rest. Throughout he showed complete disregard for his own personal safety.

Captain William Fotheringham, M.B., R.A.M.C. (S.R.).

Finding no suitable position for an aid post in the captured lines, he established one in an open trench, where he attended to the wounded for four days and nights under constant shell and gas shell attack. His courage and devotion set a fine example to all those working under him.

Captain Charles Marsh Gozney, R.A.M.C.

For conspicuous gallantry and devotion to duty in attending to the wounded under heavy shell fire. By his courage and total disregard of personal danger he set a brilliant example to all around him and greatly encouraged the wounded.

Captain Archibald McCausland, C.A.M.C.

At great personal risk he crawled through a small opening into a dug-out which had been blown in by hostile shell fire, dressed the men there, and afterwards attended to all the wounded in the locality under continuous heavy shell fire. His courageous action saved the lives of several wounded men.

Captain Laurence Abel Mackenzie, M.B., R.A.M.C.

Whilst at work in a dressing station a shell came through two roofs, killing and wounding five out of his party of six. Though severely shaken himself, he organized the dressing station and carried on with the work under very heavy shell fire for two days, showing a magnificent example of grit, courage, and devotion to duty under exceptionally trying circumstances.

Captain Gordon Archibald Macpherson, C.A.M.C.

For conspicuous gallantry and devotion to duty in collecting and tending the wounded under heavy shell fire. His promptness and devotion in collecting stretcher cases in dug-outs when it was impossible to evacuate them at once undoubtedly saved many lives.

Captain Arthur Dysant Nelson, New Zealand Medical Corps.

He remained for three days continuously on duty under very heavy shell fire, attending to the wounded of his own and many other units. Owing to his advanced position and untiring energy many lives were saved.

Captain John Fox Russell, R.A.M.C.

He showed the greatest courage and skill in collecting wounded men of all regiments, and in dressing them, under continuous shell and rifle fire.

Captain Andrew Harvey Cameron Smith, C.A.M.C.

Following his battalion closely in its attack he displayed the greatest courage and skill in establishing aid posts at the nearest possible points, regardless of his own personal safety. Though his posts were frequently under heavy shell fire the completeness of his medical arrangements, and the quickness with which aid was available, proved invaluable to the wounded. His work at all times has been marked by the same devotion and gallantry.

Captain Henry Joste Smith, M.B., R.A.M.C.

He followed his battalion in the attack, and attended to the wounded all day and night under very heavy fire of every description. It was due to his courage and splendid devotion that so many of the wounded were brought in.

Captain Ernest Talbot, M.B., R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty as battalion medical officer. Having established his aid post in a shell hole which was under direct hostile observation, he carried out his work under very heavy fire, showing wonderful organization in his evacuation of the wounded.

Captain Robert Taylor, R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty in establishing bearer posts and an advanced dressing station under heavy shell fire. It was due to his excellent arrangements that all the wounded were attended to and evacuated with the utmost regularity and dispatch.

Temporary Captain Charles Bannigan, M.B., R.A.M.C.

A dug-out having been blown in at some distance from his aid post, he ran to the spot at great personal risk under heavy shell fire and attended to the wounded, saving one man's life. His conduct on all occasions has been marked by the greatest courage and devotion.

Temporary Captain David Sands Brough, M.B., R.A.M.C.

He worked unceasingly when in charge of two bearer subdivisions. Under very heavy fire he again and again led his bearers to the wounded, setting a fine example to all.

Temporary Captain Eric William Craig, R.A.M.C.

During the night he repeatedly led the bearers beyond our front line under heavy fire. By his example and courage he was the means of rescuing many wounded.

Temporary Captain Alexander Dick, M.B., R.A.M.C.

When in medical charge of the regiment during an attack he was forced to establish his aid post in an open trench, where he carried out his duties for two days and one night under heavy shell fire and in terrible weather. He never left his post except to attend to wounded who could not be brought in, and it was owing to his energy and heroism that the wounded were safely removed from the battlefield.

Temporary Captain Ernest Eugène Herga, R.A.M.C.

When in command of an advanced bearer post he displayed the greatest gallantry and skill in bringing the wounded through heavy hostile barrage, twice crossing the open under machine-gun fire to rescue wounded men. By his skilful organization and great personal courage under fire the evacuation of the wounded was efficiently carried out.

Temporary Captain George Robertson Lipp, M.B., R.A.M.C.

He organized a party of bearers and went out under heavy shell fire and repaired the road, which had become impossible for ambulances. Later, when his post was heavily shelled, he remained and attended all wounded in the vicinity, thus setting a splendid example to all.

Temporary Captain James McDonnell, R.A.M.C.

When the village was being shelled, a number of men were buried and badly wounded. He superintended a party and worked for three-quarters of an hour, and succeeded in rescuing them. This task was carried out under continuous shelling.

Temporary Captain Hugh Ross Macintyre, M.D., R.A.M.C.

When in command of a bearer party he led his men repeatedly through heavy hostile barrage until all the wounded had been carried into safety. He was fearless in the place of danger, and by his coolness and courage he showed a splendid example to his men.

Temporary Captain Thomas Holmes Ravenhill, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in collecting and evacuating wounded under heavy shell fire, notably during a gas attack, when his coolness and judgement saved very many casualties.

Temporary Captain David Henry Russell, M.D., F.R.C.S., R.A.M.C.

When in charge of a bearer division he showed the greatest energy and complete disregard for personal safety in his untiring and successful efforts to locate the wounded and to attend to them. His devotion saved many lives, and on many occasions he has displayed the same gallantry under fire.

Temporary Captain Laurence Lancaster Satow, R.A.M.C.

He established a dressing station within effective range of the enemy's position, where he attended to the wounded throughout the day and the following night under fire the whole time. It was entirely owing to his disregard of danger and his devotion to duty that many of the wounded were collected and evacuated.

Lieutenant Arthur Gerald Phillips Wills, R.A.M.C.(S.R.), attached Cheshire Regiment.

He remained at his aid post under heavy shell fire for eighteen hours without rest, by his gallantry and fine example encouraging his bearers to work continuously, until the last case was safely evacuated.

Temporary Lieutenant Ernest Francis Rimington Alford, R.A.M.C.

He has on all occasions shown the greatest courage and disregard for danger when attending wounded under fire, and in many cases in the open.

Temporary Lieutenant Robert Beattie Martin, R.A.M.C.

He showed the greatest gallantry in attending to the wounded under very heavy fire at a moment when the enemy had turned machine guns on to them. He displayed the utmost fearlessness and skill in getting most of them away into a place of safety.

Assistant Surgeon John Wilson Woodsell, I.S.M.D.

He displayed great courage and determination in tending the wounded under very heavy fire. His devotion to duty saved many lives.

The Distinguished Conduct Medal is bestowed upon seven non-commissioned officers and one private of the R.A.M.C., one private of the New Zealand Army Medical Corps. A bar to the Military Medal is granted to three non-commissioned officers and two privates of the R.A.M.C., one non-commissioned officer each of the Australian Army Medical Corps and the New Zealand Army Medical Corps. The Military Medal is awarded to two members of the Queen Alexandra's Imperial Military Nursing Service (Reserve), and one of the Territorial Force Nursing Service; to nine non-commissioned officers and eighteen privates of the R.A.M.C., thirteen non-commissioned officers and nineteen privates of the Australian Army Medical Corps, five non-commissioned officers and eight privates of the New Zealand Army Medical Corps, and one private of the Canadian Army Medical Corps. Two non-commissioned officers of the R.A.M.C. also receive the Meritorious Service Medal.

MENTIONED IN DISPATCHES.**MESOPOTAMIA.**

A supplement to the *London Gazette* issued on August 15th contains a list of officers and others whose services have been brought to notice by Lieut.-General Sir Stanley Maude, Commander-in-Chief Mesopotamian Expeditionary Force, as deserving of special mention. The list includes the following medical officers:

Royal Navy.

Surgeons: R. G. Elwell, F. G. E. Hill, M.B.; J. C. Kelly, M.D.; J. P. Shorten.

Staff and Head Quarters.

Surgeon-General F. H. Treherne, C.M.G., F.R.C.S.Edin., A.M.S.

Army Medical Service and Royal Army Medical Corps.

Colonel W. H. Starr.

Temporary Colonel W. H. Willcox, C.B., C.M.G., M.D., F.R.C.P.

Brevet Colonels: M. H. G. Fell, J. M. Sloan, D.S.O., M.B.

Lieut.-Colonel (acting Colonel) H. M. Morton, M.B.

Lieut.-Colonels: J. H. R. Bond, A. R. O'Flaherty, L. Wood, W. A. Woodside.

Temporary Lieut.-Colonel T. P. Legg, M.B., F.R.C.S.

Major (acting Lieut.-Colonel) A. W. Gibson.

Majors: A. H. Burgess, M.B., F.R.C.S.; D. S. Skelton, D.S.O.; N. D. Walker, M.B.

Brevet Major T. J. Mitchell, M.B.

Captains (acting Lieut.-Colonels): E. T. Burke, M.B. (S.R.); W. J. Tobin.

Captains: L. D. Bailey, W. Bisset, M.B.; T. K. Boney (S.R.); F. C. Cowtan, L. Dunbar, M.B.; A. H. Gosse, M.D.; T. J. Hallinan, M.B.; J. S. McCombe, M.B.; W. McNaughtan, M.B.; W. K. Morrison, M.B.; D. C. Pim (S.R.); E. P. A. Smith, M.B.; G. N. Smyth (S.R.); A. Watson, D.S.O., M.D.

Temporary Captains: W. M. Badenoch, M.B.; F. R. Barwell, H. Cordner, M.B.; R. D. Davy, M.B.; R. C. T. Evans, M.B.; C. M. Geddie, M.B.; A. L. George, J. Hewat, M.B.; J. Macqueen, M.B.; E. W. S. Martin, M.B. (killed); G. Robinson, G. W. Spencer, M.B.; G. W. Stanley, N. Tattersall, M.D.; D. McD. Wilson, M.B.

Lieutenants (temporary Captains): A. F. I. Patterson, R. R. Thompson.

Temporary Lieutenants: L. W. Evans, D. H. Hutchinson, M.D.; J. Neligan, M.B. (deceased).

Temporary Quartermasters and Honorary Lieutenants: C. Hunt, J. S. Moore, G. B. Walker, M.C.

Indian Medical Service.

Lieut.-Colonels (temporary Colonels): G. B. Irvine, C.B.; W. H. Ogilvie, M.B.; C. N. C. Wimberley, M.B.

Lieut.-Colonels: F. W. Gee, M.B.; E. V. Hugo, M.D., F.R.C.S.; T. B. Kelly, F.R.C.S.E.; R. H. Maddox, M.B.; F. O. N. Mell, M.B.; H. G. Melville, M.D., F.R.C.S.E.; B. Nauth, E. L. Perry, F. H. Watling, M.B.

Brevet Lieut.-Colonel (temporary Colonel) G. Browse, M.D. Brevet Lieut.-Colonels: S. Anderson, M.B., C. M. Goodbody, D.S.O., F.R.C.S.I.

Majors (temporary Lieut.-Colonels): J. D. Graham, M.B.; W. H. Hamilton, D.S.O., F.R.C.S.

Majors (acting Lieut.-Colonels): L. J. M. Deas, M.B., F.R.C.S.E.; A. B. Fry, M.D.; W. D. A. Keys, M.D.; J. C. H. Leicester, M.D., F.R.C.S.

Majors: M. N. Chaudhuri, M.B.; F. P. Connor, F.R.C.S.; S. R. Christophers, C.I.E., M.B.; H. Falk, M.B.; S. R. Godkin, F.R.C.S.I.; W. F. Harvey, M.B.; A. W. M. Harvey, M.B.; R. A. Lloyd, M.D.; H. M. H. Melhuish, D. Munro, M.B., F.R.C.S.E.; T. G. F. Paterson, M.B.; A. H. Proctor, M.D.; T. S. B. Williams, M.B.

Captain (acting Lieut.-Colonel) H. R. B. Gibson, M.B.

Captains: C. H. N. Baker, H. H. Brown, H. Chand, C. A. Godson, P. F. Gow, D.S.O., M.B.; C. G. Howlett, M.B.; G. G. James, M.B.; G. R. Lynn, M.B.; L. H. L. MacKenzie, M.B.; S. H. Middleton-West, M.B.; P. S. Mills, M.B.; A. H. Napier, M.B.; J. J. H. Nelson, M.D., F.R.C.S.E.; J. A. S. Phillips, C. H. Reinhold, F.R.C.S.E.; N. S. Sodhi.

Lieutenant B. H. Singh.

Temporary Lieutenants: S. D. Billimoria, A. J. D'Souza, R. C. Malhotra, M.B.

Indian Subordinate Medical Service.

Senior Assistant Surgeon and Honorary Captain H. G. C. Mills.

Senior Assistant Surgeons and Honorary Lieutenants: E. J. Archer, H. V. Dewey.

1st Class Assistant Surgeons: A. E. Clarke, H. J. J. Garrod.

2nd Class Assistant Surgeons: E. A. Cotton, G. W. Doyle, P. J. McGrath, S. C. Raphael.

3rd Class Assistant Surgeons: J. M. M. Brown, J. S. Gloria, A. E. Mathews.

4th Class Assistant Surgeons: A. N. De Monte, J. G. Goodman, R. D. Mason, J. P. McGuire, S. W. A. Moul, W. H. Thyne, A. R. Underwood.

The list also contains the names of 6 members of the Queen Alexandra's Imperial Military Nursing Service, 16 of the Queen Alexandra's Imperial Military Nursing Service Reserve, 5 of the Queen Alexandra's Military Nursing Service, India, 9 of the Territorial Force Nursing Service, 13 of the British Red Cross Society, including Lieut.-Colonel J. Gould, M.B., and 21 sub-assistant surgeons of the Indian Subordinate Medical Service.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed in Action.

SURGEON PROBATIONER A. M. HORSEY, R.N.V.R.

Surgeon Probationer Arthur Mather Horsey, R.N.V.R., was killed in action on August 9th, aged 23. He was the only son of Mr. G. Mather Horsey, of Midford, Hertfordshire. He was born in 1893 and educated at Rugby and at Cambridge, where he graduated B.A. in 1916, and had passed his first M.B. He had served as a dresser in the 1st Eastern General Hospital at Cambridge for a year, and joined the navy in November, 1916.

ARMY.

Killed in Action.

CAPTAIN H. ACKROYD, M.C., R.A.M.C.

Captain Harold Ackroyd, M.C., R.A.M.C., who has been killed in action, was born at Southport in 1877. He was educated at the University of Cambridge and Guy's Hospital, and graduated B.C.Camb. in 1903, M.A., M.B. in 1904, and M.D. in 1910. He subsequently held the posts of house-physician at the General Hospital, Birmingham, and of house-surgeon at the David Lewis Northern Hospital, Liverpool, was at one time a research scholar of the British Medical Association, and worked for several years in the research laboratories, Cambridge. He received a commission as temporary lieutenant R.A.M.C. on February 15th, 1916, was attached to the Royal Berkshire Regiment, and was promoted to captain on completion of a year's service. In the autumn of 1916 he was awarded the Military Cross for conspicuous gallantry and devotion to duty. He was slightly wounded on July 31st, but remained on duty. He was killed on August 11th. He leaves a widow and three children.

CAPTAIN F. R. ARMITAGE, D.S.O., R.A.M.C.

Captain Frank Rhodes Armitage, D.S.O., R.A.M.C., was killed in action on July 30th, while attending the wounded, aged 34. He was the eldest son of Dr. Auriol Armitage, and was educated at Wolverhampton Grammar School, at Oundle School, where he went with a scholarship, and at Pembroke College, Cambridge, where he gained a classical scholarship in 1902, took his B.A. with honours in the Science Tripos in 1905, and graduated M.B. in 1909, after taking the M.R.C.S. and L.R.C.P.Lond. in 1908. He was also at the London Hospital, and after acting on the resident staff there, joined his father in practice at Wolverhampton. On August 7th, 1914, he took a commission as lieutenant and medical officer in the 3rd North Midland Brigade, R.F.A., went to France early in 1915, and was promoted to captain on completion of a year's service. He received the D.S.O. on July 18th, 1917, and returned to France the next day. He was attached to the Royal Field Artillery when killed.

CAPTAIN J. C. HARRIS, R.A.M.C.

Captain Joseph Cecil Harris, R.A.M.C., attached to the 3rd North Midland Field Ambulance, was killed recently at a casualty clearing station. He received his education at the Dental Hospital and the University of Birmingham, and took the diplomas of L.D.S.R.C.S.Eng. in 1906, and M.R.C.S. and L.R.C.P.Lond. in 1910. He was a member of the British Medical and of the British Dental Associations. He was in practice as a surgeon dentist in Wolverhampton prior to the war. He took a temporary commission as lieutenant in the R.A.M.C. on April 1st, 1915, and was promoted to captain on completion of a year's service.

CAPTAIN B. M. HUNTER, R.A.M.C.

Captain Bentley Moore Hunter, R.A.M.C., was reported as killed in action, in the casualty list published on August 15th. He was educated at Glasgow University, where he graduated M.B. and Ch.B. in 1909. Taking a temporary commission as lieutenant in the R.A.M.C., he was promoted to captain after a year's service, and was attached to the Cambridgeshire Regiment when killed.

LIEUTENANT A. B. ROSS, R.A.M.C.

Lieutenant Andrew Beaconsfield Ross, R.A.M.C., was killed in action on August 6th. He was the eldest son of Mr. James Ross, late of Balblair, Edderton, and of Pollo,

Delny, Ross-shire, and was educated at Edinburgh University, where he gained the Vans Dunlop Scholarship in Surgery and Physiology, and graduated M.A. in 1898, M.B. and Ch.B. in 1902, and M.D. in 1906. After acting as house-physician of the Royal Infirmary, Edinburgh, and of the Hospital for Sick Children, Great Ormond Street, and house-surgeon of Glasgow Maternity Hospital, he went into practice at Ashton-under-Lyme. He took a temporary commission in the R.A.M.C. in August, 1916.

Died of Wounds.

CAPTAIN R. L. HENDERSON, A.A.M.C.

Captain Ronald Lennox Henderson, Australian Army Medical Corps, was reported as having died of wounds, in the casualty list published on August 16th. He was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1903, and after serving as house-surgeon and house-physician at the Cumberland Infirmary, Carlisle, went out to Australia, where he was in practice at Crow's Nest, Queensland, till he joined the Australian Imperial Forces.

CAPTAIN C. W. TREHERNE, R.A.M.C.

Captain Claude William Treherne, R.A.M.C., died of wounds on August 12th, aged 29. He was the son of Surgeon-General Sir Francis Treherne, K.C.M.G., and was educated at St. Thomas's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1912. After acting as senior obstetric house-physician at St. Thomas's, and as house-surgeon of the West London Hospital, he served as one of the medical officers of the British Red Cross Society in the Balkan war of 1912-13. He took a commission as lieutenant in the Special Reserve of the R.A.M.C. on August 21st, 1914, and was promoted to captain after a year's service.

CAPTAIN H. D. WILLIS, M.B., R.A.M.C.

Captain Hugh Duberley Willis, M.B., R.A.M.C., died on August 12th of wounds received in action. He was the fourth son of Captain H. G. Willis, late R.H.A., of Glenfall, Gloucestershire. He received his medical education at the University of Manchester, took the diploma of L.M.S.S.A. in 1912, and graduated M.B., Ch.B., Victoria University, Manchester, in 1913. He took a commission as temporary lieutenant in the R.A.M.C. on August 10th, 1915, and was promoted to captain after a year's service.

Wounded.

Major J. S. Y. Rogers, D.S.O., R.A.M.C. (T.F.).

Major S. B. Smith, D.S.O., R.A.M.C.

DEATHS AMONG SONS OF MEDICAL MEN.

Arnold, Charles Vernon, Flight Lieutenant R.N., only son of Captain Arnold, R.A.M.C., War Hospital, Dartford, at Chingford, on August 16th, aged 23.

Beatty, A. H. W., Second Lieutenant Manchester Regiment, eldest son of Dr. J. Bensley Beatty, of Harrow, killed July 31st, aged 29. He was born in 1887, joined the army early in the war, and had served at Festubert and at Loos.

Burnett, L. C., Lieutenant R.N., second son of Surgeon-General Burnett of Richmond, Surrey, killed in action on August 10th while attached to the Royal Garrison Artillery.

Claremont, Frederick Victor Leszinski, Second Lieutenant Royal Garrison Artillery, son of the late Dr. Claremont, of Southsea, killed August 14th.

Evans, Rev. Geoffrey Magand, M.C., Chaplain to the Forces, son of the late Dr. Samuel Evans, killed August 12th, aged 35. He was educated at Marlborough, and had been attached to the Marlborough Mission, and before he joined the army was curate at St. Mary's, Tottenham. He had served in the Militia, in the South African war, and subsequently in the Welsh Regiment.

Shand, John James Fraser, Second Lieutenant Royal Garrison Artillery, only son of Fleet Surgeon Shand, R.N., killed August 6th, aged 19.

Solly, A. S., Captain Royal Field Artillery, eldest son of Major Ernest Solly, M.B., R.A.M.C., an ex-mayor of Harrogate, aged 23. He had been wounded about a year ago.

MEDICAL STUDENT.

Tulloch, John, Private, Royal Scots, reported missing on September 15th, 1916, now presumed killed on that date, aged 21. He was the eldest son of the Rev. W. H. Tulloch, United Free Manse, Fortingall, and before joining the army was a medical student at Edinburgh University.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

England and Wales.

THE HEALTH OF LONDON.

(Concluded from p. 197.)

School Children.

As in 1915, the special efforts of the older men and the women already employed as school doctors made it possible to engraft successfully into the school medical service new temporary officers, and to carry out with considerable success the work of medical inspection. During the year 256,847 children in the age groups were brought before the school doctors in elementary schools, and 88,415 were found to need treatment for one or more defects. The improvement in the general condition of the older children, which was a marked feature in the previous year, was maintained. The results of inspection are analysed in detail by Dr. C. J. Thomas, and compared with those of the three previous years. It is gratifying to find that the steady improvement in clothing and footwear and in cleanliness show no falling off, and the same is true of the nutrition of the children. The hardships of war have not been allowed to affect the general condition of the children, or to interfere with the growth of that care for their welfare which has distinguished recent years. In the words of the report, "a community that can thus protect its children while putting forth the most prodigious martial efforts the world has ever seen, must be sound to the core." The heavy work of school nurses has borne fruit in a continued improvement as regards cleanliness; the number of children brought to the cleansing station has steadily increased.

Under the heading of "medical treatment" we learn that the work previously undertaken has been continued, and furthermore that two new dental centres have been set up. The number of children receiving treatment under the Council's arrangements was 111,456, an increase of more than 8,000 over 1915. In addition, 181,000 re-inspections were made of children who at primary inspection had been found to be ailing. Closer co-operation has been effected between the maternity centre authorities and the school medical service.

Not far short of a million examinations were made for vermin with positive results in 25 per cent. There was a large increase in scabies among school children during the year, of which the cause was supposed to be infection from soldiers returning on leave from the front.

Although much dental defect was found, the steady improvement in the children's teeth recorded in recent reports was well maintained in 1916. A conspicuous feature of the results of medical inspection was the marked decline in the number of children referred for treatment for tonsils and adenoids; this decline still continues, and the figures for the present year are the lowest yet recorded. As usual, a large number of children failed to reach the normal acuity of vision—this was especially marked in girls. The figures for visual defect showed some increase over those of the previous year, perhaps due to loss of some of the facilities for hospital treatment of errors of refraction.

Two open-air schools at Shooters Hill and at Birley House continued their activities. Dr. Kerr, after a careful study of the record cards of the children, has compared the results with those relating to children in playground classes and in the ordinary schools. He finds that the open-air school children show a stationary weight for the first three months, and after that a comparatively rapid and steady increase.

Under the head of "infectious diseases" Dr. Hamer discusses at some length the epidemiological relationships and geographical distribution of diphtheria and scarlet fever. For the first time on record notifications of diphtheria actually exceeded those of scarlet fever for the whole year, and from September onwards this excess was marked. The reason for this unique situation was the exceptionally low incidence of scarlet fever. With regard to the suggested influence of excessively wet weather in this direction, Dr. Hamer refers to Sir John Moore's note in the JOURNAL of February 10th (p. 207) on the possible indirect effects of gunfire upon the rainfall of 1915 and 1916: "It would be indeed," says Dr. Hamer, "a strange result of the European war if it should be proved that dust due to explosion of shells was in part responsible for the notable falling off in the admission of cases of scarlet fever to Metropolitan Asylums Board hospitals."

The report is much shorter than we have been accustomed to in recent years, but there is much of interest in the 42 folio pages, and it is easy to find one's way about it although there is no index.

LECTURES ON VENEREAL DISEASES IN BRIGHTON.

The committee of the Brighton Town Council responsible for the venereal diseases campaign recently arranged for a short series of lectures to men, and another to women, on various points connected with venereal diseases. Invitation tickets were issued to medical men and women, to clergymen and to social workers of all descriptions, the object of the courses being to instruct those who later on would be likely to be addressing audiences of cadets, of soldiers, or of young men and women. The first lecture to both men and women was delivered by Miss March, B.Sc., who took as her subject the responsibility of parenthood, and handled a difficult subject with great tact and judgement. The other lectures to women were on venereal disease by Miss Douie, M.B., on the report of the Royal Commission by Miss Wakefield, and on social prevention by Miss Douglas. The lectures to men were on venereal disease by Mr. E. B. Turner, F.R.C.S., and on social prevention by Mr. E. R. T. Clarkson, F.R.C.S. Mr. Turner's address was delivered in his well-known vigorous style, and was exceedingly telling, though some of the medical members present considered that he rather exaggerated the dangers of the average case of syphilis or gonorrhoea. The audiences, though rather smaller than was desirable, undoubtedly greatly appreciated the many important and telling points which were put before them. It is to be hoped that the council will see its way to continue this excellent work, and arrange for further lectures to be given later. The venereal department at the Royal Sussex County Hospital has now been opened for the treatment of patients.

Ireland.

SALARIES AND THE COST OF LIVING.

At a recent meeting of the Clogher guardians Dr. G. A. Pringle, who has resumed his duties after a lengthy period of service in the Royal Army Medical Corps, wrote acknowledging receipt of £32 12s. 6d., including £10 to help to pay his substitute. Whilst thanking the Board for its kindness and generosity to him during his leave, he went on to point out that the salaries paid to the dispensary medical officers in Clogher Union were quite inadequate for the present cost of living. The guardians, he thought, would admit that the cost of all necessities of life was at least double what it was some years ago. This had been generally recognized by all public bodies, and the injustice to employees was met by increase of salary or payment of an annual bonus during the continuance of the war. He was sure the guardians would not be less just and generous than other public bodies, and that the medical officers could confidently leave the matter in the Board's hands. On the suggestion of the Chairman the Board decided to leave over the consideration of Dr. Pringle's letter for a larger meeting.

VACCINATION.

The Enniscorthy Board of Guardians and District Council forwarded for the adoption of the Rathdown

guardians a resolution reiterating the demand for the extension of the conscience clause of the Vaccination Acts to Ireland. They had decided to abstain from further attending the meetings of both bodies so long as the Local Government Board persisted in the enforcement of the Acts as they stood. The Chairman said an Irishman had as good a right to exercise his conscience as an Englishman, and that was his only objection to vaccination. On a show of hands the resolution was approved.

Canada.

THE CANADIAN MEDICAL ASSOCIATION MEETING.

THE forty-eighth annual meeting of the Canadian Medical Association was held at Montreal on June 13th, 14th, and 15th, in the beautiful medical building of McGill University; more than three hundred members attended, many of whom had travelled long distances to be present. The Association owing to the war had not met for two years.

Presidential Address.

In his presidential address, delivered after the annual dinner, Dr. A. D. Blackader, acting dean of the medical faculty of McGill University, reminded his hearers that it was just fifty years ago since the Canadian Medical Association was formed, at a meeting arranged by the Quebec Medical Society, and held in the Laval University on October 9th, 1867, when 148 delegates from Louisville in the east to Windsor in the west were present. Much had been accomplished since then, but in some directions the aims of the founders of the Association had not yet been realized. To cite one example: Failure had attended all efforts to establish a uniform system of recording vital statistics throughout the Dominion. Dr. Blackader then went on to discuss the more important problems that in the near future would face the profession. An attitude of "cloistered retirement" was no longer possible. Rapid changes were taking place in the practice of medicine, and it behoved the profession to stick to its high ideals. National insurance against sickness or accident was a question that should be studied by the profession, so that, when the time for legislative action came, it would be in a position to co-operate with the Government. Leaders were needed who would be willing to undertake the disinterested study of social and economic questions, and committees should be appointed to report upon such matters; it was only by broad and impartial deliberation, in co-ordination with other medical associations in Canada, that the Canadian Medical Association could take its proper place as a recognized authority on all matters pertaining to its special sphere.

Medicine.

The address in medicine was given by Dr. Theodore C. Janeway, of Baltimore, on slight variations from normal structure and function, and their clinical significance. He said that in spite of the introduction of the finer methods of investigation which had given an added complexity to the work of the physician—the shifting of the modern point of view from therapeutics to prognosis, and the substitution of the ideals of the new physiology—the ultimate duty of the physician was to sift from the medley of facts laid bare by innumerable methods of examination those upon which to base a correct judgement. Utility must be combined with loyalty to the best interests of the patient or the organization for which the examination was made. To exceed the possibilities of useful application was to conduct research. Dr. Janeway touched also upon some special problems of interpretation in the examination of patients, and closed an address that was distinguished by its note of high idealism with the stirring words: "You of the Canadian profession have borne the burden and heat of the day with a nobility to which no words of mine can pay a fitting tribute. Accept my inarticulate homage. May we not fail to meet the test, and, shoulder to shoulder with you, ensure that victory of justice and mercy which alone can bring an enduring peace."

Surgery.

The address in surgery was delivered by Dr. Francis J. Shepherd, of Montreal, formerly dean of the Faculty of

Medicine of McGill University. Under the appropriate title "Past and Present" Dr. Shepherd reviewed the progress of surgery during the past fifty years, speaking particularly of the wonderful advances made during the war in the treatment of wounds, and in sanitation and preventive medicine. With a fitting reference to those who have given their lives in the great struggle, and the work of caring for the wounded that will remain to be carried on for years to come, Dr. Shepherd went on to other matters, such as the relation between the surgeon and the physician, the undue haste of the young physician to rush into print, medical and surgical quackery, and the credulity of "Ephraim wedded to his idols."

In a paper on the transplantation of bone Drs. Gallie and Robertson, of Toronto, advocated the use of autogenous bone grafting and autogenous bone in the form of plates and screws instead of metal. The results of six cases of bone grafting in old lesions in returned soldiers were given by Lieut.-Colonel C. B. Keenan, C.A.M.C. Two interesting papers were read on nerve suture for war injuries—one by Captain Parry, C.A.M.C., the other by Major S. Alwyn Smith, C.A.M.C., who has had great experience at the Granville Canadian Special Hospital. A most interesting address on the treatment of muscle and joint contractures by physical methods was given by Professor R. Tait McKenzie.

Blindness in the Newborn.

In the Section of Gynaecology and Obstetrics, after a discussion of blindness in the newborn, a committee was appointed to prepare a resolution urging upon the General Executive Committee of the association the importance of bringing the subject before the proper Federal and Provincial authorities with a view to the enactment of legislation.

Public Health.

A suggestion made by the Chairman of the Section of Public Health that the Public Health Association of Canada should be invited to associate itself with the Section was approved. A resolution was passed strongly urging upon the Dominion Government the great need for a Federal Department of Public Health; and in this resolution was incorporated, at the request of the Montreal Society of Physical Education, a request that a Department of Hygiene and Physical Education should be established under the Federal Government.

Dr. J. D. Pagé, Chief Medical Adviser of the Port of Quebec, in discussing the methods of examination of immigrants, said that it was impossible with the present staff to examine thoroughly each immigrant. The decrease in the numbers of immigrants consequent upon the war had made it possible for the medical officers to devote more time to each individual, and at present, when immigration was at a standstill, time was being devoted to the study of new methods of examination. The fault lay not with the individual officer, but with the Government for its failure to provide proper facilities. The inadequacy of these facilities was shown in July and August, 1914, when a psychologist was engaged to co-operate with the medical examiners. During these months nearly 2 per 1,000 of the immigrants examined were found to be mentally defective, a proportion far in excess of the feeble-minded rejections in any one year since 1903.

After a discussion on the teaching of hygiene a resolution was passed in favour of the inclusion of hygiene in the curriculum of all schools.

UNIVERSITY HOSPITAL UNITS.

Sir James Fowler's proposal that military hospital units should be formed which would be named after the university or medical school from which the personnel was drawn, and that these units should be given a permanent place in the medical services of the empire, is of particular interest to Canadians, in that Canada was the first to realize the inherent advantages of units composed of men with common ideals and traditions, acquainted with each other, and bound together by a love for their Alma Mater. Soon after the commencement of the war the universities of McGill, Toronto, Queen's, Laval, Dalhousie, St. Francis Xavier, and the Western University, and the Universities of Alberta and Manitoba, offered to the military authorities hospital units fully equipped, and composed for the

most part of members of each university, for service overseas in whatever field they could be of most use. The offers of the last two universities mentioned were not accepted, but units have been mobilized, equipped, and sent across the seas by each of the other universities, and an account of their formation was published in this JOURNAL at the time of their departure from Canada. In addition, in most cases funds have been established for their maintenance.

The suggestion that permanence should be given to such units, and that they should take the name of the university from which they came instead of a number, is one which, if put into effect, would be received with the greatest enthusiasm in Canada.

Correspondence.

A NEW SCHOOL FOR THE STUDY OF HEART DISEASE.

SIR,—The plea put forward by Dr. Poynton in your issue of August 11th for the establishment of a school whose aim would be "to benefit the patient, and to attempt in every way to prevent heart disease, and to guide and protect sufferers," has much to commend it, and it is not in my view seriously disturbed by the statement of facts by Sir James Mackenzie in your columns of August 18th. It appears to me that there is not such a wide difference in the views of Sir James Mackenzie and Dr. Poynton on this subject as appears at first sight. If there are shortcomings in the present new school based on Sir James Mackenzie's work, these are probably largely due to the fact that his disciples in many instances show little evidence in their writings of the wide general experience and the width of outlook that is characteristic of Sir James Mackenzie's work, and in the absence of these qualities there is a real risk that the information to be gained by increasing attention to graphic methods will arrest rather than advance our knowledge of the etiology of cardiovascular disorders. There is good reason for believing that most of the vital problems in cardiac pathology and medicine will not be solved by attention directed exclusively to graphic methods of studying the heart's action, in combination with older and better known methods of studying the circulation. Their solution demands a much wider outlook, and a more intimate study of metabolic errors, and of bacteriological processes generally; Dr. Poynton's plea is, I take it, a timely recommendation in this direction.

An interesting and valuable practical contribution to cardiac medicine appeared in your columns in 1916 from the pen of seven workers in the new school. This set forth in useful detail the beneficial effects of physical exercises in the treatment of certain cardiac disorders in soldiers, and was the subject of a leading article in your columns of that date. In that paper it is stated that the exercises adopted were "a selection from the code of army exercises." The writers did not appear to be aware that all the exercises prescribed had long been practised by those familiar with the Swedish methods of treatment by physical exercises. I was much impressed by their value, when I made a practical study of the subject nearly twenty years ago, and a useful summary of them was written at my request and appeared in the *Encyclopaedia Medica* in 1902. Unfortunately such methods have not so far appealed widely to the profession in this country, and if we may judge by the equipment of our British hospitals, the leaders in medicine in this country are largely content to rely on pills and potions of whose action little is known except their very limited value. There is great scope for the present school educating the profession on this important subject; their work in this direction would have great value both in a prophylactic and curative direction.

May I add, in conclusion, that I do not know why Dr. Poynton selected "heart disease" as the realm of medicine in which a new school is specially required. There is, in my view, much greater need at the present time for a new school for the study of intestinal disorders. There is good reason for believing that the work of this school would, *inter alia*, contribute largely to the solution of some problems in cardio-vascular medicine that are at

present studied too exclusively by graphic and other methods.—I am, etc.,

Edinburgh, Aug. 18th.

CHALMERS WATSON.

SIR,—I assure Sir James Mackenzie that I am acquainted with the work of the Mount Vernon Hospital, and I should feel myself but a poor thing if I did not take this opportunity to express my indebtedness to the results of the assiduous investigations carried out in that institution. I do not doubt that Sir James Mackenzie has followed out his cases from youth upwards, and believe if we aroused the giants of a hundred years ago they would tell us of the same devotion. I do not doubt, too, that the Mount Vernon Hospital, in common with the more ancient hospital for diseases of the heart, and every well managed hospital in London and the provinces, has done its best for its patients. That, however, is not my point. The modern trend of the study of disease shows clearly that the hospital is but one fixed point in any such scheme—a centre with radiating lines leading to other centres—such, for example, as the medical organizations connected with the health of the London County Council schools, child welfare centres, infant clinics, sanatoriums, children's aid societies, and so on.

At the most a hospital for heart affections can be but a local centre with specialized duties—duties, let me add, of immense importance, such as accurate investigation, skilled care and treatment, and advisory—and its spirit should be tolerant of the opinions of others and mindful of its own special advantages. It does not, however, need a special hospital to look after the prevention of morbus cordis and the care of sufferers. Personally I doubt whether any special hospital is well adapted for such purposes. What, in my opinion, we need, is an institution concerned with the organization of a broad investigation of the subject, and not itself a hospital. This centre would be in touch with suitable convalescent homes, for children in particular, and in touch with children's general and special hospitals, who could refer these cases to this centre for arranging the details connected with home care and convalescence. There should be a department concerned with the world's literature on the question, departments for statistics and for investigating such wide and difficult problems as the influence of housing on the incidence of rheumatism, the influence of climate, of school strain on chorea, etc. Again, should we wish to discover the relative value of enucleation of the tonsils in the rheumatic, instead of one investigator attempting this in one hospital it should be possible to collect the records from all important hospitals, and so accelerate vastly our funds of knowledge. Similarly, the influence of early nephritis upon the heart and blood vessels could be dealt with on a large scale. The value of long convalescence could be estimated, etc. I will not use your valuable space further, for it is clear to every doctor, I believe, that if we wish to be in the van of progress the time has passed when hospitals can be looked upon as more than one element in the study of disease. In fact, I hold that, so far as London is concerned, what is euphemistically termed the *esprit de corps* of hospitals has been and is one of our greatest obstacles to progress.

Naturally the evolution of a scheme on these lines requires much care and power of organization, but it should be a means of bringing the entire medical profession in closer touch with one another, and should bring the technical hospitals nearer to the intelligent but necessarily amateur public. There are many problems, and no one has put this more forcibly than Sir James Mackenzie, that the doctor in general practice could throw light upon had he these centres for broad research to aid him. I am convinced that general hospitals cannot unaided work out these problems; the staff has its duties for which it has been appointed, and its duties to colleagues and students to carry out. A general hospital devoted to special research spells ruin to its power as a general school, for it may take years to advance medicine one little step which can be explained in fifteen minutes. In the meantime we must educate students, however imperfectly, in a general knowledge of medicine. Doubtless, if they could be educated at special hospitals they would benefit if they first learnt the fable of the belly and its members and then were taken from place to place in aeroplanes.—I am, etc.,

London, W., Aug. 18th.

F. JOHN POYNTON.

THE AIMS OF BRITISH MEDICAL POLICY.

SIR,—It is generally as well to know, or even to have a vague idea of, the goal one is aiming at. I fail to find any well defined ideal in all the discussion about medical reform. May I, therefore, outline as briefly as I can what appears to be a condition we could strive for in the certain assurance that it would benefit mankind and do us no injury?

In the first place, look at the present condition of things. A multiplicity of public authorities dabbling in medical matters, and no one head. A body of professional men striving to earn enough to live on, and therefore each competing against the other for lay popularity, and using all the arts he knows to attain that end, while he preaches the nobility and disinterestedness of "Medicine." The great lights earn much, and have time to do their work thoroughly; the small ones earn a living, and to do so have to work at such a pressure that they cannot give every case the time it ought to have, to say nothing of record-keeping. The result is that many men are unable to take care of their own health, and wear out or die prematurely, leaving dependants destitute or nearly so, to say nothing of the loss in health to the general public.

Look again, and see the environment of the patient—a cottage or room, perhaps crowded; the father laid by with pneumonia; the income of the family now reduced to 10s. a week (insurance money); the nursing to be done by the wife, who has to be up day and night in consequence. The man refuses to go into hospital because of a superstition he has that it is a home of experiments, and he will not come out alive. Is that a picture to be proud of? Yet it is a true picture. What could be worse? Is it not a State's duty to see to its improvement, and give—nay, insist that the gift be taken—the people a better chance of recovery?

Now for the other side, a quite possible condition under the State. There would be State hospitals, with dispensaries attached, in every district (small hamlets being linked together). These would have a sufficiency of doctors attached, and their services would be free to those who needed them. The conditions of the service would be such as to attract a sufficient number of suitable men, this being a most important item if any success is to be obtained. They would have a salary free from professional expenses, and a pension after a certain age, or in case of death a pension for their dependants. Instruments of all kinds would be provided, as also medicines, which would be dispensed on the premises.

Acute cases would all be treated in hospital, the patients being compelled to go there if necessary. Records would be kept, and useful medical histories would therefore be obtained for the greater part of the population, from which most valuable information could be obtained for the advancement of knowledge. The work would tend to become much better than is now possible in a vast number of cases, for the simple reason that men would have more time and better conditions to work under. This would be all to the benefit of the patient and the State. There would be only one qualifying examination, that of the State. Specialism could be more easily encouraged and practised.

The great thing that would have to go would be the patient's choice of doctor, but I doubt whether it is so valued as it is supposed to be.

I have tried to be brief and to put much into a letter. If I am somewhat ambiguous or indefinite, I ask for the reader's indulgence. I have tried to picture a scheme that I feel convinced is possible, and would be to the country's good—a condition of things that I believe must come sooner or later in some form.—I am, etc.,

Mumbles, August 18th.

F. DE COVERLY VEALE.

SIR,—Now that a Ministry of Health is to be instituted, it is clearly the duty of the medical profession, which is responsible for the health of the people, to formulate proposals, as the best interests of the public are also the best interests of the profession, for a nation's health is a nation's wealth. The welfare of the nation demands that the doctor shall be competent, and the General Medical Council registers the qualifications, thereby certifying competence, for which a charge of £5 5s. is made, but nothing more is done. Would it not be wiser if now a leaf was taken out of the book of the sister profession,

Law, and an annual registration fee instituted protecting the public as well as the profession against illegal practice, as quackery undermines the health and destroys the physique of the nation, for surely Parliament would recognize that the preservation of the lives and the health of the people should be at least of equal importance with the guardianship of their property?—I am, etc.,

Harrogate, August 18th.

CHARLES GIBSON.

A STATE MEDICAL SERVICE.

SIR,—The larger part of the rank and file of the profession are only interested in the subject of a State medical service as it affects the treatment of patients under the Insurance Act, and in the arguments and recommendations that are made in regard to the establishment of a Ministry of Health the fact appears to be overlooked that a State medical service already exists, consisting of medical officers of health, school medical officers, tuberculosis medical officers, maternity and child welfare medical officers, factory and workshops medical officers, and Poor Law medical officers. This service as it exists throughout the country is notoriously badly organized, the units of administration being irregular, the responsible local governing bodies incompetent, the position of the officials largely inoperative, and personally difficult and unfair, the whole showing a lamentable want of co-ordination, economy, and effectiveness of result. The central management of this service also is highly unsatisfactory, being vested in two or three indefinitely constituted "boards," the chief one of which has shown itself unable to put into force the powers with which it is legally endowed, has failed to obtain other powers that it should require, and has shown itself effete and spoiled by unhappy modes of procedure and precedents established on grounds of expediency and self-preservation against criticism. In contradistinction to an unwavering maintenance of principles and unquestionable propriety.

Here there is ample material for the establishment of a Ministry of Health that requires no postponement on account of the war, but whose urgency in some respects is greater because of the war, and immediate opportunity should be taken to get on with it, as it will take some time to get it into thorough working order, and after the war the time of Parliament is likely to be much occupied for years to come. In any case, the scope of such a ministry must increase with time, and its bounds must be left elastic for that reason; and if it really were essential to postpone the settlement of the medical insurance business that would be possible, though it is hard to appreciate the idea that there is anything to oppose a businesslike consideration and settlement of the matter at the present time, or that this will prove easier at some future time.

Lord Rhondda has recently made public the cause of his failure to introduce a bill for the establishment of a Ministry of Health. It was owing to the want of accord amongst certain prominent officials, backed by their several departments, which rendered it impossible for the bill to be carried in Parliament without serious dissension and opposition. One is unable to form an opinion either upon the virtues of his measure, or upon the validity of the grounds of the opposition of the objectors, in absence of knowledge of the substance of the bill and of the objections, neither of which have been published. It is certain, however, that any such bill will have to embrace both powers and persons, so far as the latter cannot be superannuated.

The business will have to be run in departments, and several heads of these departments are likely to be required. As to who shall be at the head of the Health Ministry, the jealousies of the existing men in office might be overcome by an appointment from without. The free publication of the lines of argument taken up by one and another would be likely to find due correction in public opinion. At present the public is in the dark as to the exact inner meaning of Lord Rhondda's failure, and requires to be enlightened.

Lord Rhondda appears to have relinquished the task of forming a Central Health Ministry on the promise of Mr. Lloyd George that he will exert his unique influence to bring such a ministry into being. The subject is of more pressing national need than that of education. It is a matter of life and death, and of numbers and strength of the population, and the hope must be that the Premier is

taking the matter in hand, and that the right parties are already engaged in drafting the comprehensive measure that will successfully meet the requirements of the position.—I am, etc.,

August 13th.

M.O.H.

SIR,—In your issue of August 11th a letter written on this subject is asterisked: "Our correspondent has not advanced his argument that a whole-time salaried State medical service would be a benefit to the nation." Possibly a statement of my own case will give some furtherance to the idea.

I practise in normal times in a country district and hold the following appointments:

1. Poor Law medical officer; paid by Guardians, Local Government Board.
2. Public vaccinator; paid by Guardians, Local Government Board.
3. Police surgeon; paid by County Council.
4. Panel; paid by County Council.
5. Medical referee, Workmen's Compensation Act; paid by the Home Office.
6. Examiner of recruits (now extinct); paid by the War Office.

To these may be added several semi-public appointments, such as medical referee to insurance companies.

All these different and scattered forces combine to increase the work of the practitioner, by want of cohesion and the multiplication of reports, accounts, and so on. With all this it is found necessary for school medical officers to inspect the scholars in those schools within my area, thus creating an additional authority to confuse and confound the multitude.

Then a parish medical officer (in England and Wales) has practically nothing to say in regard to sanitary matters (unless, indeed, he is fortunate enough to work in harmony with the M.O.H., and I may say that this has been my privilege), and whatever he may know, discover, or advise is voluntarily imparted and therefore concessional, excepting, of course, the bare notification of infectious disease.

All these contending influences and bewildering authorities hamper and irritate and are not conducive to efficient and related work, whereas if grouped under one central department, it is easy to see that a firmer grip could be maintained on the public health. Instead of the little allowances from this one and that one, let a head authority pay a substantial salary and get thorough and interested work done. Thus I suggest that the district medical officer perform duties as under:

1. Attend the poor.
2. Attend the panel.
3. Attend the police and concomitant calls.
4. Public vaccinator.
5. Sanitary adviser.
6. Certifying factory surgeon.
7. School medical officer.

The question of private practice, insurance appointments, etc., could be independently dealt with. The private practitioners would have ample scope.—I am, etc.,

Jos. WM. GILL, M.D., D.P.H.,

August 12th.

Captain, R.A.M.C.

A RESERVE FOR WINTER.

SIR,—May I suggest to the Central Medical War Committee that there is another duty they might very ably take over now that the recruiting of medical men is almost finished?

Their former work has been done so thoroughly that an adequate medical service can only be kept going in my district by the continuous good health of every medical man that is left. Holidays are almost an impossibility, and after three years' continuously heavy work the chances of one or other of us falling sick are greatly increased. The senior members of the profession are each a year older, as indeed, we all are.

I consider that some reserve of doctors should be arranged for who can assist when called on by the Local Medical War Committee. Some men are doing an astonishing amount of work, but we cannot do impossibilities, nor can we help one another as formerly. Unless some provision is made for the coming winter, it must occur that the medical service will, in places, utterly break down.—I am, etc.,

Ashford, Kent, Aug. 11th.

FRANK COKE, F.R.C.S.

PROMOTION IN THE R.A.M.C. SPECIAL RESERVE.

SIR,—With reference to the article *re* promotion, etc., of officers of the auxiliary medical services, in the JOURNAL of July 28th, may I call the attention of the Naval and Military Committee of the Association and of Mr. Churchill's Committee to the very extraordinary position of the majors R.A.M.C. Special Reserve, who may not be promoted to the rank of lieutenant-colonel and higher? Why? If anything, they are better qualified for the higher rank than their colleagues in the Territorials. It will be noted that this rule does not apply to the combatant officers of the Special Reserve, who have not in most cases any professional qualifications, and yet are promoted to the higher ranks. In 1915 all majors of the R.A.M.C. of three years' service and upwards were promoted lieutenant-colonels.

In justice to the Special Reserve officers, all who have done three years as field officers, and who are under the age of, say, 50, should be promoted to lieutenant-colonels.

As a body they have done extremely good work in this great war, and if the committee prevail on the War Office to rectify this very obvious omission I feel sure the service will regard it as a great compliment.—I am, etc.,

August 1st.

AN OBSERVER.

PAY OF OFFICERS R.A.M.C. (RESERVE).

SIR,—The following figures show the exact receipts of a Special Reserve officer (captain) during three years of active service. They sufficiently dispose of the statements which have been made in Parliament that either his war bonus or his allowances bring him to the same level of pay as a temporary officer. The war bonus is added in, but has not been paid, nor can it be until the end of the war. I am naturally aware that a committee is considering these matters; perhaps it will be interested in these figures.

Pay and Allowances of Special Reserve Officer (Seven Years' Service).

	1914-15.	1915-16.	1916-17.

-----------------------	---------	--------	--------

So in three years my patriotism has cost me £170 in cash, not to mention losses incidental to starting at a moment's notice. I know of no compensating advantages.—I am, etc.,

August 10th.

CAPTAIN R.A.M.C.(S.R.).

MEDICAL STUDENTS IN AND OUT OF THE RANKS.

SIR,—May I be allowed to repeat my question of July 21st—namely, Will medical students who gave up their studies at the call of their country be granted any facilities, when they come back, for shortening the time normally required to complete their studies and examinations? This is an urgent matter, and ought to be answered without delay.

At most universities special efforts were made by the staff to urge medical students to join the colours. Whether this was wise, in view of the great need for doctors, is

open to serious question. But few of us at that time looked forward to three or four years of war. Most of the students, to their honour, required no urging. Those few, however, who sat tight and were blind and deaf to their country's call are now enjoying the benefits conferred upon them by the patriotism of others. Are the university authorities going to sit tight and be blind and deaf to the claims of those brave men who risked all?

It will be a fearful struggle for these men, after two, three, or four years in the field, to sit down to their books again, and they will need all the encouragement that can be given to them. The knowledge that three or four years must elapse before they can qualify, whilst those others are reaping the reward, will not exactly encourage them.—I am, etc.,

Birmingham, Aug. 6th.

J. A. AINSWORTH.

THE TREATMENT OF SCABIES AND PEDICULOSIS.

SIR,—In the cure of disease the use of agents combining simplicity with effectiveness and rapidity deserves the closest attention of practitioners, but the medical mind sometimes overlooks the less complicated methods in favour of others that are roundabout or unnecessarily laborious.

The treatment of scabies by chlorine gas, as ably stated in the *JOURNAL* of July 28th by Captains G. H. Clark and H. S. Raper (p. 113), is one that they have shown to be useful so long as the patients themselves are prevented from being "gassed," but it none the less exposes them to the risk of serious danger, to say nothing of the trouble and fuss involved.

It is evident that unguents are better avoided in getting rid of both classes of insects, though ultimately effectual in time, which, however, is always unnecessarily long.

Against pediculi liquor hydrargyri perchloridi quickly kills the living parasites, and spirit washes off the nits, both in very brief time. Against the itch insect painting the body once a day with liquor calcis sulphuratus is equally certain and rapid. Both of these methods I have used often during the last forty years, and until May last I knew of nothing better or more simple, the time required being from one to three days as a rule.

My object in writing this is to draw attention to the paper by Captain J. A. Gunn, R.A.M.C.(F.), of Oxford, in the *JOURNAL* of May 5th, in which he recommends vests and pants of butter muslin (costing only a few pence each) wrung out of the following: Naphthalin 1½ oz., sulphur powder 1½ oz., benzol or petrol 1 gallon. The garments dry quickly, and, being worn next the skin, are fatal to lice and itch insects by the ingredients residing in the texture.

I could give illustrative cases to the point, but the paper of May 5th gives all the necessary details, and if readers be not convinced of the utility and facility of the treatment advised, nothing that I can add will avail. What is required only is the receptive and appreciative mind.—I am, etc.,

RUSHTON PARKER,

Professor of Surgery in the University of Liverpool,
Lieut.-Colonel R.A.M.C.(F.), Mersey Defences.

Liverpool, July 29th.

THE LATE DR. HACKMAN OF PORTSMOUTH.

SIR,—Will you allow me space enough to say that I am endeavouring to wind up the Hackman Memorial Fund, and shall be glad therefore if any member who wishes to subscribe will do so at the earliest opportunity? The amount so far raised is something over £620. A full statement will be issued to subscribers in due course.—I am, etc.,

Brandon House, Mile End, Landport,
Portsmouth, August 21st.

JAMES GREEN.

Obituary.

LIEUT.-COLONEL A. F. S. CLARKE, M.D.,

R.A.M.C.(RET.)

LIEUT.-COLONEL ALFRED FREDERICK STAFFORD CLARKE, R.A.M.C.(ret.), died at Bexhill on August 11th, after a year's illness, aged 78. He was educated at Manchester Royal Infirmary, and graduated M.D.St. Andrews in 1860, also taking the M.R.C.S. and L.S.A. in the same year. He entered the Army Medical Department as staff assistant-surgeon on April 1st, 1861, became surgeon in March, 1873, surgeon-major on April 1st, 1873, and retired with the honorary rank of brigade-surgeon on September 1st, 1882.

DEPUTY SURGEON-GENERAL DON writes: Lieut.-Colonel A. F. S. Clarke was widely known to the service seniors and contemporaries of his day; but to the great majority of medical officers now serving he can only be little more than a name. Yet he was an officer of mark in his time, as one always striving for the honour and reputation of his department, having a high sense of duty, and skilful in his professional work. To those who, like myself, had the privilege of his personal friendship, he was endeared by his engaging cheery manners, patent sincerity, and amiability of character.

He entered the service in 1861, and was appointed first to the Black Watch and afterwards to the Royal Artillery, in which he served for years; for some time he was in medical charge of the famous Royal Horse "A" Battery, or the "Chestnut Troop." The last five years of his full-pay service was in the "sanitary" while I was in the "medical" branch at head quarters in the War Office.

In 1882 he accepted the retired list in order to take up the important medical charge of the Royal Military and Staff Colleges, a position he occupied with conspicuous success for twenty-two years, until final retirement under the age limit of 65. He thus became known to thousands of officers and cadets passing through Sandhurst and Camberley, many of whom had good cause for gratitude for his skill and attention during sickness; it is stated as remarkable that in the many years of his charge no one lost his life from sickness. His sanitary training also enabled him to cope so successfully with an epidemic of diphtheria at Sandhurst as to elicit the thanks and praise of H.R.H. the Duke of Cambridge.

I may here record what is now little known, or half forgotten, that in 1881 Clarke and I, with the full concurrence of the Director-General, Sir William Muir, together inaugurated the first annual dinner of the medical department; it was a venture towards unification, at first received with some coldness by old regimental medical officers who had corps dinners of their own, and with banter and ridicule from some military authorities who then affected to regard the "doctors" as a sort of "camp followers," unfitted for such collective effort; but the dinner was a success, and developed into the annual gathering of a consolidated Royal Army Medical Corps.

After final retirement, Colonel Clarke took an active interest as a trustee on the Committee of Management of the Army Medical Officers' Widows and Orphans Fund, a friendly society, now over a century old, which has attained a very strong financial position, and offers to its (voluntary) members, at reasonable actuarial rates of subscription, substantial bonuses and annuities to their widows.

He was entirely laid aside, from heart affection, about a year ago, and his death was due to this cause. He leaves a widow and only son, Brigadier-General I. L. I. Clarke, East Yorkshire Regiment, who has recently done distinguished service at the front in France.

DR. T. DYSON WALKER, who was an honoured member of the medical profession of St. John, New Brunswick, Canada, where he had been in practice since 1892, died at the Massachusetts General Hospital, Boston, on July 22nd. He was born at St. John in 1857, the eldest son of Colonel Thomas Walker, M.D. He was a descendant of Elizabeth Yates, a sister of the famous Pendrell brothers, who were instrumental in saving the life of His Majesty King Charles after the battle of Worcester, and for this Colonel Walker drew a pension from the Treasury. Dr. Walker was a graduate in arts of the University of New Brunswick and in medicine of the University of Edinburgh (1891).

LIEUT.-COLONEL JAMES DAVIDSON, Bombay Medical Service (retired), died at Turriff, in the first week of August, aged 77. He was a native of New Deer, and was educated at Aberdeen University, where he graduated M.A. in 1861 and M.B. and C.M. in 1864. He entered the I.M.S. as assistant surgeon on September 30th, 1867, became surgeon on July 1st, 1873, surgeon-major on September 30th, 1879, and brigade-surgeon-lieut.-colonel on April 2nd, 1892. He retired on December 3rd, 1892. He served in the Abyssinian war in 1867-68, in the general hospital at Zoula (medal), and in Southern Afghanistan in 1880, in medical charge of the base hospital at Pir Chowky (medal).

The Services.

GRATUITIES OF OFFICERS, R.A.M.C. TERRITORIAL.

A CORRESPONDENT tells us that he has been informed that the yearly gratuities earned by the officers of the R.A.M.C., Territorial, are "washed out" in the event of an officer's death in action or on service.

* Our correspondent's information appears to be incorrect. The matter is governed by Army Order No. 406 of 1915, which deals with the issue of gratuities to Territorial Force officers. It provides that the gratuity is issuable to the estates of officers who die while serving. Attention may be specially directed to paragraph 5 of the Order.

EXCHANGES.

OCCUPANT R.A.M.C., ophthalmic centre, France, wishes to exchange with officer holding similar appointment in United Kingdom.—Address, No. 2709, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

R.A.M.C. Exchange wanted. M.O. to a reserve park (horse transport) in France desires exchange with M.O. of a home service unit. Write for particulars to M.O., No. 2 Res. Park A.S.C., B.E.F.

Medical News.

THE Wellcome Historical Medical Museum will be closed for cleaning from September 1st to the 30th inclusive.

A NEW periodical entitled *Laboratorio* has recently appeared in Spain. It is devoted to the biological sciences and experimental medicine. It is published by G. Domenech-Reig y Cia, Pelayo, 24, Barcelona.

MR. GEORGE W. BRACKENRIDGE of San Antonio, Texas, has given £10,000 to enable Columbia University to open its doors to women students of medicine this autumn. The existing buildings will be extended to provide additional laboratory facilities for work in chemistry, pharmacology, pathology, and bacteriology.

Two or three years ago we reviewed Dr. J. P. McGowan's report upon his *Investigation into "Louping-ill" or "Trembling"* (BRITISH MEDICAL JOURNAL, August 7th, 1915, p. 221) which is somewhat prevalent amongst sheep in Scotland and the north of England. The names "louping" or "leaping-ill" and "trembles" were given by stock-owners because some of the affected animals show nervous excitement by leaping off the ground, and others exhibit muscular tremors. Sir Stewart Stockman, of the Board of Agriculture and Fisheries, has contributed to the *Journal of Comparative Pathology and Therapeutics* an account of special investigations carried out by him into the etiology and epizootology of this disease with special reference to the "tick theory," which has been the subject of much discussion, but has never received general acceptance. The infective agents of tick-borne diseases are protozoan parasites. The result of Sir Stewart Stockman's close investigation of the fluids and tissues of sheep affected with louping-ill has been to furnish strong evidence against the idea of a protozoan organism carried by ticks being the cause of this malady.

THE Howard Association was formed fifty years ago to promote efficient methods for the prevention and treatment of crime and juvenile delinquency. In the annual report for 1916, now published under the title of *Crime and its Treatment*, the committee notes that the two outstanding features of the year were a decrease of nearly half the number of adult offenders, and an increase of one-third in the number of juvenile offenders. Before the war the prison population of England numbered 16,727; at the present time it is somewhere about 9,000. On the other hand, whereas before the war there were some 37,000 delinquent children a year, there are now 50,000. All the reformatories and industrial schools are reported to be full. The association's office has become a clearing-house for information on this matter, and a report, entitled *The Child and the War*, was prepared by the secretary, and published for the benefit of judicial and educational authorities. Two facts were revealed by this survey—a shortage of adult leaders of children's organizations, and an overlapping of effort. Steps were accordingly taken to strengthen and co-ordinate the work of children's societies in each area. With regard to the decrease in the prison population, which has occurred in Scotland and Ireland as well as in England and Wales, three main causes are given—enlistment of many habitual petty offenders; the restrictive orders of the Liquor Control Board and of

justices and military authorities; and the great demand for labour, rendering employment easy and well paid, and resulting in ability to pay fines. The association considers that the dull, mechanical routine of the reformatory industrial schools ignores the individual, and does not tend to produce the type of citizen which life to-day demands.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Antiology, Westrand London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecya, Westrand London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

It appears to be necessary again to remind correspondents that no notice can be taken of contributions not verified by the writer's name.

QUERIES.

X. Y. Z. asks for advice as to the nature and treatment of the following condition in a child aged 3½ years: A marked linear blush, about half an inch wide, over the left cheek, extending along the line of Stenson's duct, from the ear to the mouth, appears whenever the child masticates its food. There is no paralysis of the face nor anything to point to a cause for this condition, which has evidently been present since child was an infant. It would seem as if the parotid secretes into the tissues instead of into a duct.

W. M. B. asks for advice in the treatment of epilepsy in a boy, aged 9, who had had several major convulsions; potassium bromide 30 grains a day was given, and the major attacks stopped, but minor attacks supervened—as many as twelve to fifteen in twenty-four hours, and have not been affected by continuance of the bromide. Should bromides be continued? Some authorities recommend perseverance with them; others, not to give bromide at all. Our correspondent also asks for references to recent literature.

LETTERS, NOTES, ETC.

THE ALLEGED PERILS OF URIC ACID.

DR. D. DUNCAN (London, S.W.) writes: "Atophan" (the composition of which is stated to be 2 phenylchinolin 4 carbonic acid) eliminates uric acid as shown a few hours after the first dose. The symptoms at once diminish, and soon disappear, as does the excess of uric acid on continuing the treatment. This week, he adds, the first consignment of a British substitute has reached me. I tested the preliminary sample and found it innocuous and effectual. The makers will doubtless introduce it to the profession in the usual manner.

ROYAL EARLSWOOD INSTITUTION FOR MENTAL DEFECTIVES.

DR. A. G. NEWELL (Harringay, N.) asks any medical man who has votes in the election for cases for admission in this institution, or can influence any votes, to consider the case of Miss Veera Cherry at the election in September. It is a most deserving case, and any further particulars he will gladly give.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under
Each additional line
A whole column
A page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Remarks

ON

THE TREATMENT OF THE WOUNDED
KNEE-JOINT,

MADE AT THE OPENING OF A DISCUSSION AT ROUEN,

BY COLONEL H. G. BARLING, C.B., A.M.S.

If any apology is needed for discussing wounds of the knee-joint it will be found in the number of such cases occurring during the war, and in the deaths, the amputations, the loss of function in the joints resulting therefrom, which have been and still are a matter of constant anxiety to us all.

If we had attained the acme of success, or if we were agreed on the lines of treatment to be adopted, the discussion to-day would be unnecessary. But neither of these conditions can be claimed; success such as we desire is still far from us, and whilst there is agreement as to treatment up to a certain point, then comes divergence.

I have no cut and dried programme of treatment to place before you, for although I have seen and treated a considerable number of infected knee-joints in military hospitals at home I recognize that the problem of treating such cases out here is a different one, and I have only had a brief experience in France.

I will in the first instance give figures showing the general results of treatment in the Rouen area during the months June to December, 1916. No one is better aware than I am of the objections which may be offered to the study of surgical conditions by statistical methods, nor am I forgetful of the fact that classification such as I have adopted is necessarily in some degree artificial. Recognizing these limitations I still believe that something may be learnt from the figures, and I should like here to express to the commanding officers and to the surgical specialists of the various hospitals my best thanks for the trouble they have taken in searching out the notes of cases over a prolonged period, practically from July 1st to December 31st, 1916, though in some instances a rather longer period is covered.

The figures from all hospitals are added together, so that we obtain the average results. Each hospital will be able to compare its results with the average, and will learn whether its amputation rate and its rate of mortality is as good as or worse than its neighbour's. From my own experience I know that it is a healthy discipline occasionally to get out the figures of one's work in some particular line; general impressions are not always reliable, figures may supply a useful corrective.

Before considering the statistics it is necessary to remember that from them are excluded—

(a) All cases in which owing to the healthy appearance of the wound and the quietude of the joint no operative measures were resorted to; and

(b) Those cases in which conservative measures were impossible and early amputation was imperative.

One other point should also be remembered—it is that circumstances entirely prevent any record now of the final condition of the patients comprised in my table.

The first thing that strikes one in the figures is the very high proportion of cases in which excision of the wound, removal of bone when necessary, removal of any retained foreign body, irrigation of the joint and closure by suture has been followed by a perfectly satisfactory healing without further interference. The proportion of these cases requiring further intervention is 25.5 per cent., and it is, I think, reasonable to believe that free use of the joint is likely to result in a large majority of those in whom the primary operation was successful. (See table, items 4 and 5.) In the next group, where complete closure was not possible or was deemed inadvisable, and in which the wound was packed, we have not such a good account. The results, though, are still very good, especially when we remember that this group pretty certainly includes the worst cases of injury to the bones entering the knee-joint. Here the proportion of cases in which further operative interference was required is 38.4 per cent. (See table, items 6 and 7.) Although again we have no definite figures to guide us, I am satisfied from my experience of such joints in the past that very useful joint

function may result in many cases; this is confirmed by reply cards returned by patients to the surgeons out here who have operated upon them.

I think we shall agree that excision of the wound, removal of bone when required, removal of foreign body, suture of the wound, if possible, and packing as an alternative in selected cases, is the programme to be followed.

In the reports which have been kindly sent to me on methods adopted I find some divergence on details—one surgeon washes out the joint with one antiseptic, one with another, but the majority seem to favour eusol. In a considerable number of instances materials such as formalin and glycerin or ether have been injected and retained in the joint cavity. A few surgeons pack the joint with urea and speak favourably of the results obtained. One operator makes a point that may be worthy of attention; for the purpose of washing out the joint he makes a separate incision at some distance from the wound of entry, thus securing that at all events he drives nothing septic into the joint.

I question whether it much matters what fluid is used to wash out the joint, the main advantage is the mechanical cleaning out of septic material, fibrin and blood clot, but this should be thoroughly done, and I question if it is thoroughly effected unless there is a free opening; the use of cannulae for this purpose seems to me insufficient. Any antiseptic now at our disposal capable of destroying the infection is capable also of damaging the endothelium of the joint and so of reducing the resistance of the tissues to infection. On one point I am sure we shall all agree—it is the immense importance of carrying out with the most scrupulous care and technique the primary operative interference.

I turn now to another vital question we have to consider in connexion with the wounded knee-joint. I have already shown what a considerable proportion of cases settle down after the primary operative measures. When this does not happen and the joint is swollen and painful, the temperature and pulse are rising, evidences that the infection has not been overcome by the early treatment, what are we to do? Are we to be content with aspiration of the joint and irrigation or injection with an antiseptic fluid? Personally, I would deprecate this line of treatment and would only resort to it if the fluid showed only a low corpuscular element, a moderate polymorph count, and a sparsity of infective organisms—conditions which will rarely be found. Mere aspiration is apt to be followed by a breaking of infection through the capsule of the joint and a spread into the surrounding tissues, a grave addition to the patient's troubles most difficult to overcome.

Regarding aspiration as rarely a wise measure, I mention three other courses open to us: (1) Free opening up of the joint; (2) excision of the joint; and (3) amputation. Of arthroectomy I say nothing, partly because I have seen little of cases treated by this method and partly because it does not commend itself to my judgement.

I. Free Opening of the Joint.

By free opening of the joint I mean a lateral incision on each side to the extreme limits of the great bursal pouch and well to its lateral margins. Some surgeons go further, and in order to empty the posterior portion of the joint divide the lateral ligaments right back to the posterior margins of the femoral condyles. If ankylosis results the division of the lateral ligaments does not matter, but if some mobility is retained there is left a certain want of stability in the limb which somewhat interferes with its usefulness. For this reason I would reserve division of the lateral ligaments until a later stage of ill-doing in the septic joint showed that it is really called for, and especially would I resort to it when drainage of the posterior part of the joint is required. With free opening of the joint I would associate treatment by Carrel's method. The introduction of, say, four of his tubes, with the instillation of Dakin's fluid on the usual plan, gives greater promise of successfully combating septic joints than any other measures I have seen used. It does not seem necessary or desirable to retain the tubes for an indefinite time inside the synovial sac; in a few days, if possible, they should be so arranged as to lie outside the joint cavity. This will not relieve us of the duty of constantly watching the patient for any fresh focus of infection, especially at the postero-lateral aspects of the joint. Whatever the method of treatment adopted

its success will in the end depend upon the constant watchfulness and personal care of the surgeon, which is, of course, a hard saying when there is great pressure on the hospital staff.

II. Excision of the Joint.

This operation has not been much in favour at the hospitals in Rouen; at some it has not been resorted to at all, but I have collected forty-two cases. Of these, eight were followed by amputation, and the deaths, either with or without amputation, were thirteen. I do not regard this as a fair picture of what may be obtained by excision. In some cases I am satisfied that excision was resorted to at too late a stage, in the hope of escaping from the disagreeable alternative of amputation—a hope which was frustrated later on, amputation then being performed in patients who were ill able to withstand a further severe traumatism. If we are to consider excision at all it must not be as an alternative to amputation; there is a case to excise and there is a case to amputate, and these must not be confused. One of the really difficult tasks which a surgeon has to undertake if he adopts excision is to select suitable cases.

Some of the results recently reported of early excision tempt one to adopt that line of treatment, but it will be well to remember before doing so what our own experience has taught us, that a large number of such early cases recover under conservative treatment, and with useful joint function in some instances. Another point which makes one hesitate is the lack of knowledge of the final utility of the excised limb. One method suggested in a recent paper involved a wide separation of the divided bones of about two inches and the bone ends being maintained apart until all sepsis had disappeared. From the experience of excision of the knee in civil practice failure of bony union is under these conditions likely to occur, and the union by fibrous tissue may be very unstable. Firm union after excision has always appeared to me to depend mainly on early and accurate approximation of the sectioned bones. If bony union fails, further operative measures, by freshening of bony surfaces or by bone grafting, may yet succeed, but even if they do they involve for the patient the anxiety of a further operation, a rather prolonged convalescence, and possibly further shortening of an already short limb. Conviction as to the value of excision of the knee will only arrive when we know the final results obtained. To sum up this question of excision, if we excise very early we may get immediate satisfactory results, but we do not know what the final results will be, and we shall be excising joints which in a considerable number of cases may recover under conservative treatment, some with useful movement. If we excise in a later period we encounter a considerable death-rate, a high amputation rate, and uncertainty as to the final utility of the limb in the remaining cases.

III. Amputation.

The third course available when the primary conservative operation fails is amputation. I have heard amputation deliberately advocated as the correct immediate treatment if there is good proof that the sepsis has not been controlled by the primary intervention, mainly on the ground that our chief business is the saving of the patient's life, and that early amputation would be attended by a very low rate of mortality.

No one would dispute that early amputation would have a low death-rate, but such a course is repugnant to the patient and to the surgeon, and many limbs would be sacrificed which are now saved. Even though the knee be ankylosed or the limb shortened considerably, there is no comparison between the disability of the man with an artificial leg and that of one who retains his own, rigid though it be. For the sake of the individual whose earning capacity and whose enjoyment of the amenities of life will be seriously diminished, as well as for the sake of the State, we must spare the limb when we dare. But the onus falls on us of deciding in each individual case that we have pursued conservatism as far as is reasonably safe. All the convictions as to the advantage of a damaged limb over an artificial one, all the sentiment which makes amputation so repugnant must be kept firmly in hand. It is a sad epitaph for any patient that his surgeon, out of too kind consideration, deferred amputation until it was

too late to save the patient's life. If we are perfectly frank with ourselves, few of us will be able to say that we have not erred in this direction. Reference to the figures will show that amputation followed in 13 cases after failure of excision or arthrectomy, and in 151 other cases not so treated; the total number of amputations was 164, or 19.4 per cent. The percentage of amputations has varied considerably at the different hospitals. The total mortality from all cases has been 72; the percentage is 8.5.

1. Total cases of injury to knee operated on	845
2. With bone injury	438
3. Without bone injury	407
4. Wound excised and closed	322
5. Cases under (4) requiring further operation	82=25.5%
6. Wound excised and packed	336
7. Cases under (6) requiring further operation	128=38.4%
8. Excision of knee	42
9. Arthrectomy, partial or complete	15
10. Excisions or arthrectomies amputated	13=22.8%
11. Deaths after excision or arthrectomy	13=22.8%
12. Amputation without excision	151
13. Deaths under class 12	49=32.4%
14. Total amputations	164=19.4%
15. Total mortality	72= 8.5%

NOTE.—One hospital with a large number of cases was unable to separate the cases under items 4 and 6.

EARLY TREATMENT OF GUNSHOT WOUNDS OF THE KNEE-JOINT.*

BY

TEMPORARY COLONEL H. M. W. GRAY, C.B., A.M.S.

THE splendid results which many of you are achieving make one wish that all knee cases requiring operation could be treated in casualty clearing stations, but during a push this is out of the question, so that a selection must be made of all cases likely to be able to travel to the base without serious risk.

Before going further, I desire to say that in no other class of cases is technique and judgement in early treatment reflected so much in the results obtained. The surgeon who exhibits the greatest care in technique, especially when removing foreign bodies and infected tissue, whether of the soft parts or of the bone, gets the best results. So good are these that, recently, several cases which, in the earlier part of the war, would have been submitted to primary amputation, on account of the extent of the damage to bone, have been sent down the line with every likelihood of having not only a useful limb, but a useful movable joint also. Conservative operations on gunshot wounds of the knee-joint, however, in order to be successful, demand such care that I think they should be handed unreservedly to the surgeon in the unit who has demonstrated special skill in their performance. I venture to lay special stress on this, because many really good surgeons fail to appreciate even what is essential in totally excising the soiled wound in such cases. To this cause I attribute most of the failures.

All wounds of the knee joint should be splinted by the field ambulance units. This is most important, because movement may aggravate infection already present, or introduce infection where none existed, and in both ways prevent successful conservative treatment.

Excision of Wound.

The ultimate object of treatment of these cases is to secure mobility of the joint. Our primary object in the casualty clearing station must, therefore, be to secure asepsis. The surest and quickest way of doing this is to excise completely, if possible *en masse*, all tissue which is definitely or probably infected. This having been done, the wound remaining can be treated on aseptic principles. This, of course, entails the exclusion of all instruments, gloves, towels, etc., which may have come in contact with infected parts. A large percentage of these wounds are sutured, and heal by first intention. A suitable plastic operation may have to be done. In most cases it is advisable to provide drainage "down to but not into" the joint cavity or bone fragments.

* Paper read at a meeting of medical officers of an army in the field.

Although, in many cases, the wounds cannot be closed, yet it is usually possible to suture the synovial membrane of the front of the joint, especially if the suprapatellar pouch is loosened from its upper and anterior connexions by finger or curved scissors, and pulled down. This point is of very great importance.

Fixation.

Fixation of the joint is essential to success in all but the simplest wounds. We have found that the best method of ensuring this is to put up the limb in a "Thomas splint outfit," just as in cases of fracture of the femur, with the exception that the extension strips are applied with the object merely of keeping the Thomas splint in position. No traction is necessary. If a back splint only is used, it must reach from the *tuber ischii* to the ankle. Shorter splints are worse than useless. The splint can be prevented from slipping by fixing each end to the skin with strips of sticking plaster. The upper strip should not encircle the limb.

Foreign Bodies.

Removal of a foreign body, lodged within or near the joint and not visible or palpable from the surface, should never be attempted without *x*-ray localization when that is available. Otherwise, probably more harm than good will be done by interference. If *x* rays are not available, these cases should be transferred without delay to a unit which is provided with an installation. Of course, if the foreign body can be seen or felt, or if synovitis is already very marked, the sooner operation is done the better.

Selection of Cases.

During severe fighting the selection of cases for operation at a casualty clearing station seems to me to depend chiefly on the size and position of the wounds, especially of entrance wounds; on the size and character of the missile, especially if lodgement has occurred, and on whether it is visible or palpable; on the size of the wound in the synovial membrane, and on whether it communicates freely with the surface wound, so that infection will occur easily; on the amount and character of comminution of bone; on the presence or absence of injury to large vessels; on whether intra-articular tension is present or absent; and, finally, on whether definite sepsis has developed or not.

Cases for Transfer to Base.

Hence, if the wound of entrance is small, especially if due to an undistorted rifle bullet, if there is no external evidence of a foreign body, if there is no comminution of bone or injury to large vessels, if there is not painful tension, and if there is no inflammation, the patient may be sent on to the base, after thorough disinfection of the skin, suitable dressing of the superficial wounds and fixation of the limb, the knee being slightly flexed, in a splint of proper length. There is no need to use the "Thomas outfit" except in serious cases, but those in which penetration of the synovial cavity is even merely suspected should be fixed in a splint.

It may be noted here that an "open" wound of the back of the joint is usually less serious than a similar one on the anterior aspect, possibly because, in the latter, sepsis is more likely to gain access during transport.

Cases for Retention at Casualty Clearing Stations.

If the superficial wound is large—even, for example, like that caused by a shrapnel ball, and especially if it communicates freely with the synovial cavity—if there is a visible or palpable foreign body which has opened the joint, if there is much comminution of bone, if there is a haematoma in the popliteal space or haemorrhage from a wound there, if there is undoubted inflammation, the case should be kept at the casualty clearing station.

On admission, the limb should be dressed, fixed in a suitable splint, and, if *x*-ray localization is required, the patient should be sent to the radiologist, who should take two skiagrams, one antero-posterior (toes pointing straight forward) and one lateral, on the same plate if possible. This method is probably the quickest and best in the circumstances. The patient is then sent to the pre-operation ward. The splint should not be removed till the patient has been anaesthetized. The strapping of the splint permits examination of the wound without moving the knee.

Operative Treatment.

I think it will be simplest, in dealing with operative treatment, to discuss the worst cases first.

Amputation.—If the injury has implicated the main vessels so that the foot is already cold and dead, amputation should be done—just above the knee if the wound is likely to remain fairly clean, and through the knee if sepsis is present and the condyles are undamaged. In the latter class of cases reamputation is frequently necessary, and when the condyles are left it can be done so as to provide the longest possible thigh stump. If, as sometimes happens, one or other popliteal nerve is shot away so extensively that it cannot be sutured later on, and if the bones are much soiled as well as comminuted, the probability is that primary amputation is the best course. If sepsis is well established in presence of much comminution, especially if there be gas gangrene, and the patient in low condition from haemorrhage or toxic absorption, amputation must be done.

Resection.—If, in less severe cases, the opposing ends of the long bones are so comminuted that smooth articular surfaces are not available, it is probably best to do primary resection in the way recommended by Colonel Fullerton.

Conservative Treatment of Fracture Cases.—If large fragments have resulted from the injury, if the patient has been got early and is in good condition, and if one is fairly sure of getting away infective material, the case should be given a chance.

Removal of Patella.—As a general rule, if the patella alone has been shattered, as happens fairly frequently, the fragments should be removed.

If possible, the synovial cavity should be closed, except for a small drainage opening, by suturing the lateral edges and aponeuroses, possibly after undercutting the synovial membrane on each side, or by loosening the suprapatellar pouch as already described. If this cannot be done, a "salt pack" should be used in the way described later. The same procedure should be carried out if concomitant injury to other bones is not extensive. It is wonderful how the infection tends to remain limited to the anterior part of the joint if the limb is thoroughly immobilized—plus a flat pad in the popliteal space.

In considering the question of amputation, these points are of great importance: the possibility of removing or neutralizing infective material successfully, the amount and kind of comminution, the concomitant injury to vessels or nerves, and the condition of the patient.

Conservative Treatment.

When conservative measures are decided upon, the following are the most important operative details:

1. Determination of the track which leads to the depth. The knee may have been bent when the patient was wounded, so that when the limb is straight the track is distorted. Excision of the track is best made when the knee is held in the same position as when injured.

2. Thorough disinfection of skin and track. The whole of the skin around the knee, and for at least six inches above and below, should be shaved and disinfected. For final disinfection I prefer picric acid (3 to 5 per cent.) in spirit. The external wound and track are disinfected (a) if not very large, by the actual cautery, or (b) by rubbing thoroughly every part with 10 per cent. iodine or picric acid in spirit. The strong solution has the effect of drying the tissues.

3. Careful and complete excision of external wound and track, including the edges of the wound in the synovial membrane, if possible in one piece. Incision, using a sharp scalpel, must be made quite clear of the deep as well as clear of the superficial wound. Pockets must not be cut into. Clipping infected tissue away piecemeal courts disaster. As the blades of the scissors are closed, infective material from their proximal parts is forced along to the distal. The least little bit of infected tissue left behind may prevent success.

4. Provision of ample access to foreign bodies or comminuted surfaces in the joint. Blind groping with the finger is to be avoided, because the foreign body or infective material is thus frequently pushed beyond easy reach, and further struggles in attempts at removal end in disaster. Incisions must be chosen, therefore, which give easiest access, and they must be free enough, even to the extent of dividing the ligamentum patellae and turning up a flap, etc.,

to enable one to see the foreign body, and obtain plenty of room for manipulation of instruments. If complete excision of the infected wound has been made under proper technique, one should be able to get first intention after suturing, however large the wounds may be.

5. Careful removal, under direct vision whenever feasible, of all foreign material, whether free in the joint or embedded in the articular surfaces. If the latter, the bone surrounding the foreign body must be carefully chiselled or gouged away, *en masse* if possible. The joint cavity is then flushed out with 5 per cent. saline, flavine solution, etc.

6. Closure of the wound in layers, using fine catgut for the synovial membrane. Drainage tubing should not project into the joint. Of course, if tubes are required for the introduction of fluid, as in the Carrel Dakin method, they should be carried to the deepest recesses of the joint, or inserted through a fresh incision. They should be removed as soon as possible.

7. If the wound in the synovial membrane cannot be closed, a small "salt pack," separate from any other which may be required for the rest of the wound, should be inserted firmly "down to but not into" the joint, and should be left until it is absolutely loose. A small tube may be placed in the centre of the pack, reaching to the synovial membrane, and it may be removed in a couple of days. If attempts are made to pull the pack away, adhesious shutting off the main cavity of the joint are likely to be broken down, and infection is then liable to occur.

8. Tendinous or ligamentous structures exposed during operation should be covered by skin and subcutaneous tissue, otherwise they are very apt to slough, and this postpones closure of the wound, and therefore prolongs convalescence.

9. If there is much effusion into or from the joint, of whatever nature, or if raw surfaces, whether of bone or soft tissue, are left in the joint, at the end of operation, a tube should always be inserted "down to but not into" the synovial cavity. Pressure of effusion—that is, tension—must be avoided at all costs, because it interferes with healthy circulation in and absorption by the synovial membrane, and these are essential to successful combating of any infection which may have been overlooked.

10. The injection of ether, formalin-glycerin, or hypertonic (5 per cent.) saline solution into closed joints, is of doubtful value. They are all irritants. Success is claimed for all three, although their actions are different. The common factor in their application is preliminary aspiration of the joint. This removal of tension is possibly the explanation of their apparently beneficial action. It is possible, however, that the injection of or washing out by a non-poisonous, non-irritating antiseptic like flavine, whose antiseptic action is enhanced by mixture of the substance with body fluids, may be of great value in many cases.

11. The paramount importance of obtaining x-ray skiagrams has already been indicated.

Haemarthrosis with Small External Wound.

I should like to discuss just one other type of injury, that which produces haemarthrosis in presence of small through-and-through wounds, and where only slight damage to soft tissues or bone is present. If the effusion cannot be aspirated, owing to the fact that firm clotting has occurred, I believe that best results will be obtained by deliberately opening the joint, by free incision on one or both sides, washing out the clot with sterile salt or flavine solution, and stitching up again without drainage. If the wounds are very small, one need do no more than sterilize them superficially. Such a blood clot, after a few days, forms excellent pabulum for the growth of organisms, and, even though it does not become infected, it is often the cause of much distress and disability in later stages, owing to formation of intra-articular adhesions. Officers at base hospitals in France appreciate the disastrous results of insidious infection in such cases. Hospitals in England have beds occupied unnecessarily long, even by non-infected cases, because, owing to the adhesions, they require skilled massage and so forth. Arthrotomy in this type must not be undertaken lightly. Technique must be perfect, else dreadful disaster is incurred.

Retention of Cases after Operation.

Operated cases should be retained for at least twenty-four to forty-eight hours. Firm compression under a very thick layer of cotton-wool and fixation in the "Thomas outfit" should be employed. I believe that a pad of wool in the popliteal space, tapering to each end, tends to prevent suppurative tracking from the back of the joint. If the joint looks quiet at the end of twenty-four to forty-eight hours, and the general condition is good, the case may be evacuated.

While the "ham" splint of the outfit is best for transport and for cases in which the wounds are in front of the joint, yet if there is a large wound on the posterior aspect, the thigh and leg should be suspended on separate slings of perforated zinc, well padded and covered with jaconet, so that access to the wound is provided without running risk of moving the joint.

Gentle passive movement, to a few degrees at first, should be begun as soon as one is certain that the parts are healing aseptically.

Sepsis.

If sepsis develops, all wounds should be opened up freely, possibly bilateral openings should be made, and the synovial cavity treated by intermittent flushing with Dakin's solution, or, which may prove to be better, with flavine solution. If improvement does not occur within twenty-four to forty-eight hours, a transverse or flap incision should be made, followed by resection, as Colonel Fullerton has advised, or, after free division of the lateral and cruciate ligaments, by packing and fixing the joint in flexion in Hepburn's aluminium splint. If the articular surfaces of the bones have been injured, the former method is preferable.

In conclusion, I would urge again the importance of rigid technique, and the necessity for thorough and complete operation. Half measures are worse than useless. "All or nothing" is a sound watchword. If the fulfilment of these principles is not possible, far rather fix their limbs properly, and send all patients on for treatment at the base.

RESULTS OF SIXTY CONSECUTIVE CASES OF WOUNDS OF THE KNEE-JOINT.

BY

W. H. OGILVIE, M.A., M.B., B.Ch.Oxon.,

SURGEON, URGENCY CASES HOSPITAL FOR THE FRENCH, MEUSE.

In the eighteen months from July 1st, 1915, to December 31st, 1916, I have received into my wards sixty cases of penetrating wounds of the knee-joint in an unoperated condition. The greater part of these were from the Verdun fighting in 1916. I exclude from analysis cases which had been opened and drained at a clearing hospital, and also a certain number which got well with no further treatment than immobilization, and in which actual penetration of the joint was not certain. Apart from these exceptions, I have included all penetrating wounds of the knee which I have treated since the opening of the hospital. They were, as a rule, received in from twenty-four to forty-eight hours of being wounded.

Classification.

The cases naturally fall into the following classes:

- A. No bony injury, and no projectile included.
- B. No bony injury, but projectile included.
- C. Bony injury, no projectile included.
- D. Bony injury, with inclusion of projectile.
- E. Bony injury of the lower limb of such gravity that involvement of the joint is only of secondary importance, no functional result being possible. Here the saving of life and, if possible, of the limb as well, is the only consideration.

As regards the probable final result, the presence or absence of a bony injury is the chief deciding factor. In classes A and B, given an aseptic result, which should be obtainable if the wound is a recent one, a good movable knee is nearly always to be hoped for. In classes C and D the result will vary from complete mobility to complete stiffness, according to the nature of the bony injury—again

always provided that treatment has resulted in the abortion of infection. Where there is serious bony injury, even partial mobility means an uninfected joint cavity.

Classes A and C differ, however, from B and D in that in the former operative interference should be avoided if possible, and if undertaken should in the first instance be limited to measures directed to cleaning the track; it is far better to leave the joint cavity alone if there is any reasonable probability of its being uninfected.

In classes B and D operation for the removal of the foreign body is necessary in the majority of cases. If, however, having traversed the joint, it is found to be extra-articular, and at the same time is small and not obviously the seat of infection, it is far better to be content with immobilization and dressings till all reaction has subsided. The projectile can then be removed aseptically at a later date.

Methods.

I have attached the greatest importance to immobilization—the most complete that it is possible to obtain. Any form of splint which rests upon the bed does not satisfy this requirement, as, however perfectly it may be fixed to the limb, any shocks or jars of the bed or its neighbourhood are communicated to the leg, while voluntary movements of the patient or necessary nursing attentions must cause at any rate some disturbance to the injured part.

In all cases of penetrating wounds of the knee-joint I have slung the whole limb from a rigid frame attached to

Fig. 1.—Blake fracture splint.

the bed. The apparatus I have employed is the form of bar splint used by Mr. Blake at the American Ambulance, Neuilly, Paris, which consists of two parallel bars of iron 9 mm. in diameter, free at the lower end, and connected at the upper end by a U piece set at an angle which fits the posterior aspect of the thigh at the level of the tuber ischii.

Fig. 2.—Footpiece as used for traction. For knee cases wood piece is screwed on.

The whole is bent out of one iron rod, and I have them made locally by a blacksmith at a cost of 3 francs. This splint is cheaper to make, easier to apply and to sling, and more comfortable in use than the Thomas knee splint. When using this splint for wounds of the knee I fit a sliding footpiece (Fig. 2) to which the foot is fastened by adhesive strapping at the time of operation. Above this I have three semicylindrical sections of thin aluminium sheeting, hinging on the inner bar and clipping on the outer one. The upper one supports the thigh, the lower one the calf and ankle, and the middle one, when unclipped, exposes the posterior aspect of the knee, and allows the most extensive dressings to be done without the slightest disturbance to the limb. The aluminium sections give a rigid support far superior to bands of flannel or canvas

Fig. 3.—Splint arranged for wound of knee-joint.

they are easily cleaned and sterilized, and they form no obstacle to x-ray examinations in the splint. The whole splint is slung by two weights running over pulleys, the upper one of about 4 lb., the lower one of about 8 lb. Those in the illustration (Fig. 4) are 75 mm. shell cases, which, used empty for the former and filled with metal fragments for the latter, give the exact weight required. The upper weight keeps the U piece constantly on the tuber ischii, and allows the splint to follow every movement of the

patient's body, as when he goes on the bedpan. The lower is adjusted so that the foot of the splint will stay in any position in which it is put, and makes it an easy matter to raise or lower it for dressings. I have several times been astonished at the way in which a case which was doing badly on a fixed splint immediately started to improve when slung in this way.

In operating, the wound is regarded as consisting of two distinct portions—the extra-articular, where infection is

Fig. 4.—Splint in use; showing manner in which the splint is slung.

parried and repair instituted by the establishment of granulations; and the articular, where infection is combated by the action of the synovial membrane and its secretion, and where the establishment of granulations, though possibly beneficial in other ways, means impairment or loss of function in the joint as such. The extra-articular wound is accordingly cleaned and drained, the articulation is cleaned, closed, and allowed to fight its own battle. Drainage means throwing the two parts into one, with a likelihood of the same process being established in

Fig. 5.—Splint in use; showing ease with which wound may be dressed.

both. The synovial membrane has a surprising power of combating infection, especially, it appears, infection by gas-forming organisms. But to give it a fair chance it must be spared all avoidable injury:

1. Extensive incisions, retracting or holding the edges with clips to see into the joint.
2. Lengthy exposure.
3. Bleeding, and the consequent swabbing of the synovial surface.
4. Application of artery forceps.

These sources of damage are all reduced to a minimum if a tourniquet is applied in every case and x-ray localization is carefully done.

5. Leaving foreign bodies in contact with it—drainage tubes or accidentally included foreign matter.

6. The use of antiseptics.

In operations for the removal of foreign bodies included in the joint the procedure has been as follows:

1. The track is excised as far as the capsule with knife or scissors, only bruised or soiled tissues being cut away. The wound is then swabbed out with 5 per cent. iodine in spirit.

2. With a fresh set of instruments the joint is now opened, blood clot shelled out, and the projectile, together with bits of cloth and loose bone fragments, removed. If the projectile is far from the entry wound, it often saves injurious handling, after excising the track, to enter the joint through a fresh incision, which may later be sutured completely, being presumably clean.

3. The joint is irrigated with about two pints of 5 per cent. saline to wash out blood, cloth, and bacteria.

4. The wound in the synovial membrane is approximated with sutures. The track, if large, may be closed somewhat, the object being to leave it a funnel shape, with its apex at the wound in the synovial membrane and its widest part at the surface. It is loosely packed with gauze soaked in 5 per cent. saline.

5. 10 c.cm. ether is injected into the joint with a needle and syringe at some other part.

6. The limb is wrapped in cellulose tissue, an excellent absorbing medium, fixed in the sectional splint, and slung while the patient is still under the anaesthetic.

Afterwards, the outer cellulose dressings are changed daily and the plug moistened with saline. In four or five days it slips out easily, and may be replaced by a small wick. Fluid always fills the joint for the first few days, but does not often require aspirating.

I have always left the joint undrained as long as possible, as a drained joint nearly always means a stiff joint. Once it is certain that the resistance of the synovial membrane to infection has been overcome, I open the joint by an incision above the patella, and a lateral incision each side as far back as possible. Rubber tubes split longitudinally—not holed, for a holed tube is soon anchored down by granulation buttons and completely blocks drainage—are inserted from the upper opening to each lateral one, passing through the joint. Good drainage is now a prior consideration to avoidance of injury to the synovial membrane. A few drops of saline are run down these tubes each day, but beyond this nothing is done. The knee-joint is too complex a cavity to offer any hope that syringing or continuous irrigation will in any sense wash it through; the only effect of these measures is to set up eddies which wash infection into places which it perhaps has not yet reached, and to start tracking along muscle planes. It is safer to ensure that such flow as there is in an outward direction; this is done by free openings and really complete immobilization.

Resistance of the Knee-joint to Gas Infection.

Two cases were remarkable in that in each instance wounds of the thigh muscles and the knee-joint, occurring in the same leg and caused by the same projectile, gave rise in the muscular tissues to a virulent gas infection and in the joint only to a serous reaction. Another case arrived twenty-four hours after being wounded with several bits of bomb in the outer side of the right lower limb. Those in the leg and thigh showed a local gas infection. One piece had penetrated the external lateral ligament and was projecting into the joint, which was tightly distended with gas. The projectile was extracted by the entry wound. On the experience of former cases, the joint was not drained, but the gas and fluid were drawn off with a trocar and cannula. A tube and funnel were then joined to the cannula, the joint repeatedly washed out with saline, and ether injected. Recovery was without incident, and on evacuation to the interior the man was walking with an almost complete range of movements, which would certainly become perfect with massage.

Results.

Clean movable joints	33
Clean joints with limited mobility	5
Stiff limbs	17
Amputations	3
Deaths	2

Three of the 60 cases belong to Class E. Their discussion does not come under joint surgery, but I have included them so as to make the series a complete one of every fresh case treated in which the knee-joint was involved. Omitting these, there are one death and two

amputations in 57 cases. The death occurred on the eighth day from an acute dysentery. The knee-joint was not only clinically clean, but *post mortem* contained only serous fluid.

Of the amputations, in one there were multiple wounds of the left lower limb. On arrival there was a cellulitis extending from the ankle to the middle of the thigh. A large bit of shell had chipped the external condyle and head of the tibia, and there was pus in the joint. Four-hourly fomentations were applied to the whole limb for a week, rendering real immobilization impossible.

In the other case I blame myself for not having discovered at an earlier date that the joint was infected. There were small wounds all over the front of the right thigh which revealed nothing to the x rays. After fifteen days I operated and found a track containing mud and gravel leading into the suprapatellar pouch, and a mild infection of the joint. His low condition made amputation advisable six weeks later.

From the point of view of the classification given above the results are:

Class A (10 cases):

Clean movable joints	6
Limited mobility	1
Stiff limbs	2
Amputation	1

Class B (19 cases):

Clean movable joints	15
Limited mobility	2
Stiff limbs	2

Class C (7 cases):

Clean movable joints	3
Stiff limbs	4

Class D (21 cases):

Clean movable joints	9
Limited mobility	2
Stiff limbs	8
Amputation	1
Death	1

Class E (3 cases):

Stiff limb	1
Amputation	1
Death	1

Owing to consideration of space, the summary of cases accompanying this article has been omitted. The illustrations are the work of Orderly E. D. Wookey, to whom the author wishes to express his thanks.

THE TREATMENT OF GUNSHOT WOUNDS OF THE KNEE-JOINT.

WITH AN ANALYSIS OF SEVENTY CASES.

BY

CAPTAIN C. MAX PAGE, M.S., F.R.C.S., R.A.M.C.(S.R.).

THE outcome of wounds of the knee-joint during the present war has, on the whole, been a source of surprise and satisfaction.

The extent of the articulation makes any general infection of it the source of profound toxæmia, and its anatomical complexity renders surgical treatment, when necessary, difficult.

For these reasons civil experience has led to a profound distrust of the ability of this particular joint to deal with infective processes. This attitude was, it appears, based on an experience of the comparatively exceptional cases in which general infection had taken place in a practically closed joint. Intensive practice under war conditions, however, has shown that when rational measures are adopted at an early period, infection of the knee and other joints can in the presence of an open wound become limited and be dealt with by the natural defences in a remarkable way.

Nevertheless, for reasons not always avoidable, general infection of the joint does occur in a certain proportion of cases—in this series, 37.7 per cent.—and the results collected for one base over five months show that we have by no means arrived at a generally satisfactory method of

treatment, for of 845 cases the amputation incidence was 19.4 per cent. and the mortality 8.5 per cent.

While views essentially common have been established on the ideal primary procedure, which aims at the relative eradication of infection, it must be admitted that as to the treatment of established infection of the joint opinions are somewhat divergent. This is not surprising when the complexity of the factors governing treatment and the difficulties of establishing the relative merit of different procedures by crucial experiments is considered. Further, in the publications on the subject there has been a lack of detailed data which would assist in the formation of a judgement. I have therefore thought it worth while to define the factors which appear to me to influence success, to tabulate a series of cases treated consecutively on consistent lines, and to analyse the results obtained.

The cases were treated at a base hospital in France, consequently the experience is limited to a definite period and no valent opinion on the end functional results can generally be formed.

The series of 70 cases was consecutive; they were treated over a period of some seven months, and only cases submitted to operation have been included. Thus all cases with clean perforating wounds remaining clean which came under observation during the period are omitted. Cases in which amputation was carried out within twenty-four hours of admission on account of gas infection or gross injury to bone, main vessels or nerves, have also been excluded (9 cases). In a fair proportion of the cases the first operation had been carried out at a casualty clearing station. When this is the case it is noted in the general table.

The following statement gives a general outline of the cases and the results of treatment:

TABLE I.

Total number of cases	...	70
Cases of articular bone injury	...	59 = 88.8 %
Cases in which the missile lodged	...	51 = 72.8 %
Cases recovering without obvious infection of joint	...	45 = 64.2 %
Amputations	...	10 = 14.2 %
Deaths after amputation	...	4 = 5.7 %
Total deaths	...	5 = 7.1 %

CLASSIFICATION OF CASES.

For the purpose of considering the treatment and prognosis, these cases may be divided in the first instance into two main groups, namely: Group I, Wounds caused by a rifle bullet travelling at high velocity; and Group II, Wounds caused by shell fragments and distorted bullets. All joint injuries may be further subdivided from an anatomical standpoint into two classes, namely:

Class A. Those in which the injury is purely synovial.
Class B. Those in which articular bone injury is also present; it is convenient to classify three types of such injury, namely:

1. Gross comminution of an epiphysis or the patella.
2. Fissuring of an articular bone—local or extending from the diaphysis.
3. "Punch" fractures in the cancellous bone of the diaphysis.

Clinically, in the later stages the number of classifications is duplicated by considering as separate types those cases in which general arthritis does or does not develop. Further subdivisions in accordance with the degree or nature of the infection, the retention or not of the missile, seem at present unnecessary complications.

THEORETICAL BASIS OF TREATMENT.

In the stage under consideration here infection of the joint is the principal danger, and the orthopaedic results, important as they are, must be regarded as a secondary consideration.

Though cases occur (eight instances in this series) in which a small missile remains in or about a joint without inducing general arthritis, from general experience it will be granted that all wounds in which a missile of any size lodges are in some degree infected. Infection is also usually present in cases of perforation by shell fragments. It is of interest to note that in nineteen of twenty-five cases of general suppurative arthritis in this series the missile was retained; in four of the remaining cases the wound was caused by shell fragments. Only in typical rifle bullet wounds does experience justify the assumption that,

on the average, whatever the anatomical injury no serious infection of the wound track has been effected. In practice the conservative treatment by fixation and simple dressing of these latter cases (Group I) leads on the whole to good results. This is not to deny that if a radical operation had been performed the result might have been equally successful, but practical considerations make exclusion of the necessity for operation desirable.

In Group II suppression of the primary infection is sometimes effected by the natural mechanisms of defence, but more commonly local infection, and often general infection of the joint cavity ensue. In the cases of local infection the synovia behaves much like the peritoneum—for example, a track freely open into the joint may often be grossly infected and yet the outlying parts of the joint and the effusion are sterile, the joint cavity being filled with a clot ("lymph") containing cells having a defensive function (some interesting observations on the prognostic value of a differential examination of these exudates have been published by Captain Barlow¹); in such cases, if the reaction of the tissues around the wound has not been unduly prejudiced by the initial injury and the infection is not of unusual virulence, recovery may be completed without general suppurative arthritis, intra-articular adhesions being formed.

However, experience has shown that if, as a routine, expectant treatment be adopted in these cases, a general arthritis, calling perhaps for amputation, too frequently follows. We are therefore forced to attempt, at a period before extension of infection has taken place, to remove in as complete a way as possible the primary infective focus and any surrounding devitalized tissues. In practice this involves excision or erosion of the wound track and the removal of any missile which may have lodged; if the bone injury is such that subsequent ankylosis of the joint is assured, a primary excision is justified.

To judge by the results in this series an operation based on these lines can be performed with success up to two or even more days after the injury, but there can be little room for doubt that the failures would be reduced if such operations were thoroughly carried out within twenty-four hours following injury, and never later.

In view of the impossibility of deciding the degree of infection present by clinical examination at the stage under consideration, I think that all cases coming under Group II should be treated, as above suggested, by a primary radical operation.

As a further means of combating infection, repeated evacuation of the joint and its injection with various antiseptics has been widely advocated; aspiration is useful at certain stages for the purposes of bacteriological investigation or for the relief of exceptional intra-articular tension, but the removal of the defensive exudate as a routine and at regular intervals seems as unreasonable as to rub away the lymph and wash out the serous exudate in an early case of peritonitis—a procedure now generally recognized as harmful. The injection of any of the antiseptics in common use into the joint cavity seems to be an equally illogical procedure, calculated to do more harm than good to the natural defensive mechanism. In this series aspiration has only been used for exploratory purposes, and in no case has any form of antiseptic been injected into the uninjured part of the joint cavity.

Thorough fixation of the injured joint in the critical period during which infection may spread is, I think, of great importance. There is no evidence which justifies us in casting on one side a procedure aiming at the provision of complete rest for the injured part, in view of its success in kindred conditions.

Established Infection of the Joint.

In established infection of the joint, especially when due to the streptococcus, the results of treatment are often disappointing. When the complication of severe bone injury is present, immediate amputation is often the only course if life is to be saved. The majority of cases offer, however, ground for more conservative measures, and many different procedures have been advocated. Tube drainage of the joint on classical lines has not proved a success; the same may be said of methods of continuous drainage; of the Carrel treatment I have not sufficient experience to be able to form an opinion.

The exposure of the whole joint surface by means of a transverse section and fixation in full flexion still has its

advocates. Four cases in this series were so treated, with poor results. It appears that the gross disturbance of the natural relationships involved prejudices the defence in really severe cases; when the method is successful one cannot help thinking that the infection would have been equally well dealt with if less drastic measures had been adopted. Colonel Fullerton, A.M.S.,² has lately suggested formal excision of the joint at this stage. The results he quotes do not, however, afford conclusive evidence of the value of the method; in accordance with general surgical principles an operation involving such an extensive exposure of new surfaces in the presence of progressive infection seems unsound. In this series no cases were treated by the method, as it had given poor results in my hands in earlier experience. I have recently had the opportunity of seeing the end results of some cases so treated, and from an orthopaedic standpoint they left much to be desired. It should be remembered that a fair proportion of cases of severe general infection of the joint treated on conservative lines recover a useful range of movement, and anything like a routine employment of excision in the treatment of arthritis is to be deplored.

Recovery in these cases is essentially due to the activity of the natural mechanism of defence, and it is the business of the surgeon to assist these mechanisms and not to lay further burdens on them. Complete fixation is the first and essential step in this direction; in my experience this can best be effected by the use of plaster-of-Paris. In the early stages the application of heat to the joint area is a sound measure; it may abort suppuration and in some cases assists the defence. Operative measures should, I think, be limited to those imposed by the direct indications of the accumulation of fluid under tension. If a bacteriological examination of the joint exudate (not of the wound discharge) shows the presence of streptococci, early incision is indicated, as this infection spreads rapidly beyond the confines of the joint capsule into the cellular planes, leading to intense toxæmia. After lateral arthrotomy a watchful attitude is maintained, the commonly occurring popliteal abscess and any other residual formations being dealt with as they are diagnosed. Further to assist the defence in these conditions, artificial immunization may be employed. This procedure was carried out in some cases in this series. It is always a difficult matter to appraise the value of such methods, but my impression is that they have often been the factor determining the success of conservative measures; in no case have they been harmful in their action. Captain W. E. M. Armstrong, R.A.M.C., was responsible for this form of treatment, and I append a note he has given me on the subject of immunization in septic wounds in general.

Note on Immunization Procedures Applicable to Septic Wounds.

The difficulties connected with the immunization of wounded patients are: The number of different organisms present, the difficulty of working in harmony with the surgeon, and the often very exhausted state of the patient.

Practically I have tried to meet these difficulties in the following manner:

1. The organisms present in wounds are usually streptococcus, staphylococcus, and members of the coliform group. The coliforms may perhaps be regarded as comparatively harmless, while the staphylococcus usually tends to localize and so is amenable to surgical methods of extirpation. The streptococcus is, however, very different, and as regards radical extirpation may be almost as troublesome as the tubercle bacillus itself. My efforts have, therefore, been almost entirely directed against the streptococcus.

2. The difficulty of working in harmony with the surgeon is very great. His proceedings in the dressing of wounds and removing foreign and dead material result in the patient receiving a series of autoinoculations which, being unstandardized and ill-timed, play havoc with an immunity mechanism which is already in a very hyper-sensitive state. On the other hand, the surgeon can be most helpful by his devices for immobilizing the affected parts. That this is one of the best methods of immunizing a patient has been abundantly shown by the excellent results obtained by the use of plaster-of-Paris. In fact, careful immobilization is often all that is required, and

inoculation methods have only been used when the fixation method fails, or is too slow in its results to save the patient.

3. The third difficulty is, I believe, a very real one. Many of the patients are so exhausted as to be incapable of that vital response which is necessary for effective vaccine treatment. I have tried to grapple with this difficulty by using passive methods of immunization. Actual treatment has been carried out by means of vaccines and Spengler's immune-body solutions. I seldom make autogenous vaccines. There is usually no time to do this, and even if there were, I prefer in a dangerous case to use a vaccine whose potency I know to one whose power can only be determined by trial trips on a patient who is too ill to be experimented upon. I use St. Mary's Hospital streptococcus vaccine, and I follow fairly closely the teaching of Wright. I have never produced in any patient a negative phase clinically recognizable, and I never give a second dose until I am quite sure that the first has exhausted its utility.

I have often obtained rather striking results, both general and specific, with Spengler's solutions. They can if necessary be used concurrently with vaccines.

The results obtained have already been stated by Captain Page. As implied above, I have only treated cases in which enlightened surgical methods have either failed or threatened to fail. Since crucial experiments are well-nigh impossible, one cannot speak in terms of absolute certainty. Nevertheless, I have little doubt that a few lives have been saved and a few limbs preserved by making use of knowledge of immunity phenomena to tip the balance in the patient's favour.

PRACTICAL PROCEDURE ADOPTED.

Prophylactic.

By prophylactic treatment is meant treatment before general infection of the joint has taken place, and ideally within twenty-four hours of the infliction of the injury.

In the case of injuries coming under Group I (typical rifle bullet perforations), no operation is undertaken. The joint is fixed on a back splint, or in plaster in a position of slight flexion at the knee and with the foot lying comfortably. The wounds are not excised, and are covered by a simple dressing. The fifteen cases so treated during the period of these observations have not been included in the tabulated cases with the exception of two, the only instances of this group in which general infection of the joint ensued. When painful intra-articular tension is present, the joint is aspirated once and evacuated as completely as possible. In such cases the primary exudate contains much blood; secondary serous exudates are not removed.

All cases in Group II (injury by irregular missiles) which came under observation within two, or sometimes more, days of the injury are submitted to operation with a view to removal of the infected and damaged area. An x-ray examination in two planes is made whenever possible; it often reveals unsuspected bone injury, and is a sufficient guide to assist in the removal of any foreign body which has lodged.

In cases of Class A (simple synovial injury) of Group II the wound track is completely excised without the removal of much skin, and any retained foreign body is removed. No attempt is made to suture the synovial membrane, but the skin edges are opposed if this can be effected without causing undue tension; when it is not possible the wound is lightly packed with sterile gauze. Any effusion into the joint cavity is usually evacuated during the course of the operation, but no deliberate attempt is made to do this unless the effusion consists mainly of blood.

In cases of Class B (articular bone injury present) of Group II the operative procedure is essentially the same, though the removal of bone in the wound track may present technical difficulties.

1. When gross comminution of the epiphyses is present, and subsequent ankylosis is assured, primary excision of the joint may be the most effectual procedure. Such an operation should only be undertaken within the first two days of injury. Leriche³ presents a strong case for the adoption of this method within the first twenty-four hours. In this series no case was considered to have come under observation early enough to justify the procedure, though excision of the patella was carried out in three cases.

2. When fissuring of the bone is in evidence, any completely detached fragment is removed and all bruised cancellous bone in the wound track is curetted away till a bleeding surface is met with. The bone wound is then packed if it continues to ooze as described below.

3. In the case of "punch" wounds of the cancellous tissue, removal of the whole wound tract can be satisfactorily effected with the curette and gouge. The foreign body is usually retained in these cases, and is dislodged from the end of the wound track. If bleeding from the cancellous bone persists, as it commonly does, after the completion of the bone operation, the bone cavity is firmly packed with dry ribbon gauze, a single wick being brought out along the wound track, and the skin wound closed on either side without tension. Gauze packs of this kind and those applied to more superficial gashes are left untouched for four or five days and then removed. They are sometimes lightly renewed for another day or so, but more often a simple surface dressing is alone applied at this period.

Fixation.

In all cases the joint is kept at rest till healing is in progress and pyrexia has been absent for about a week; gentle active movement is then encouraged. If plaster fixation has been used sufficient play will have developed in ten or fourteen days to admit of this, the splint being kept on altogether for about three weeks. The Thomas's knee splint, though convenient for wound treatment when large wounds in the thigh are present, does not fix the joint satisfactorily, nor is it easy to put the knee up in a position of flexion in this apparatus. A simple back splint is often convenient, but in difficult cases it is not sufficiently controllable, nor does it admit access to the area at

FIG. 1.—Interrupted plaster-of-Paris knee splint. The aluminium (or malleable iron) brackets which form the two lateral interruptions are joined together above by an arch passing in front of the thigh. The support of the back of the joint by fabric slings is also shown.

the back of the joint. An interrupted plaster-of-Paris splint (Fig. 1), in my experience, affords the only satisfactory method of controlling cases of excision, or those in which there is serious injury of the articular surfaces. The two sections are formed by plaster bandages. The upper section should extend to the level of the tuber ischii above, and the lower should include the foot in a comfortable position. The interruptions are formed by two laterally placed aluminium or malleable iron arches. In accordance with the position of the wounds a plaster back or sidepiece can be added. When such cannot be applied, as is common in cases of general infection of the joint, posterior support at the knee-joint level is given by two or three slings passing from arch to arch in the same fashion as in a Thomas's splint. Whatever form of fixation is used the limb can be rested on a pillow, though more freedom is given the patient if it is suspended, and this was usually done in this series.

General Suppurative Arthritis.

In the early stage of some cases the joint is hot and swollen without severe constitutional symptoms. In these circumstances, supposing the primary wound treatment to have been properly carried out, any sutures are removed, rigid fixation is maintained, and hot fomentations are regularly applied to the joint area. Not infrequently the condition will settle under this treatment without suppura-

tion. As soon, however, as a diagnosis of a more severe infection is made from the classical clinical signs or by bacteriological examination, arthrotomy is performed; in general, two vertical parallel lateral incisions are made into the most lateral parts of the subcutaneous pouch; posterior drainage is not attempted. If there is tension about the wound it is enlarged, or sometimes run into one of the lateral incisions. Any loose bone not already removed is taken away but no fresh section of bone is made, nor is excision of the primary wound or of the whole joint practised at this stage for reasons set forth above. At the completion of the operation the arthrotomy incisions are packed with sterile gauze down to, but not materially penetrating into, the joint cavity. These packs are left in for two to three days, or till such time as suppuration renders their removal easy; they are then lightly renewed till the infection is under control. Of secondary abscesses, one in the popliteal space tracking out from the popliteus bursa is most commonly seen. Any such secondary formation is allowed to develop definitely, and is then incised, evacuated, and packed with gauze for a few days. Carrel's method of wound treatment has been adopted in one or two cases only, and so no judgement can be formed, though it would appear that its value is based rather on the primary surgical technique employed than on the later.

Immunization is carried out in the most severe cases in accordance with the methods referred to above by Captain W. E. M. Armstrong.

Amputation may be called for at different stages on account of the rapid advance of the toxæmic symptoms. A circular supracondylar amputation is then aimed at, and is usually possible, unless there is serious extension of cellulitis into the thigh. All viable skin is conserved and the stump cavity is packed at the completion of the operation with plain gauze, which is left in place for four or five days.

ANALYSIS OF RESULTS IN SEVENTY CASES.

For the purposes of this series a successful result is considered to have been obtained when complete control of any infection present, as judged by the healthy condition of the wound and the entire absence of pyrexia, has been obtained. In only a minority of the cases was entire healing of the wound and complete recovery of function in the joint observed.

GROUP I.—Rifle Bullet Perforations.

As stated above, only two cases (34 and 49) of this kind are included in the series:

Case 34.—Comminution of the patella and fissuring of both tibia and femur. Patient developed signs of general streptococcal infection of the joint on the seventh day. The patella was excised. Recovery followed after three secondary incisions for residual abscesses.

Case 49.—Gross comminution of the internal condyle of the femur; entry at level of the joint line; explosive exit 3 in. higher up. Incision and removal of broken bone on fourth day; amputation on fifteenth for progressive toxæmia. Recovery.

GROUP II.—Shell Wounds.

Class A, *Synovial Injury only (11 Cases).*—All but one recovered without general infection of the joint. This case (No. 40) had a single gaping wound, 3 in. by 2 in., in the antero-external aspect of the joint. Death took place on the forty-fifth day from tetanus, four days after amputation had been carried out.

Class B, *Complicated by Bone Injury.*—The following table gives the general results of these cases, 160 in number, in relation to the three types of bone injury recognized.

TABLE II.

Type of Bone Injury.	No. of Cases.	Recovery without Infection.	Recovery after General Infection.	Recovery after Amputation.	Deaths.
1. Gross comminution of the diaphysis or patella	17	4	7	3	3
2. Fissuring of the articular bone	14	10	1	1	2
3. "Punch" wounds or grooves of surface	28	22	4	2	0

Nine cases of this nature were submitted to amputation on admission—that is, in general two to four days after injury, and are not included in the series.

The notable feature of these results is the unsatisfactory course of the cases in which there was gross comminution of the epiphysis. In no case of this type had a formal excision of the joint been carried out within a day or two of the injury, and as the results from the point of view of infection could hardly be worse, and as from an orthopaedic standpoint subsequent fixation of the joint was a necessary sequence whatever the treatment adopted, primary joint excision or erasion might be carried out with greater hopes of success.

The smaller number of cases of Type 2 gave better results though by no means ideal ones.

In case of injuries of Type 3 the recovery incidence was not unsatisfactory, and there are certain points in relation to the six failures which it is of interest to tabulate, as they emphasize the importance of the time factor in these cases.

TABLE III.

Case No.	Nature of Injury.	Days elapsing between Injury and Primary Radical Operation.
1	Foreign body lodged in internal condyle	Five.
34	Groove in external condyle of femur; foreign body retained	Three.
53	Tunnel in tibia; foreign body retained; left side. Other knee also infected	Four.
54	Entry wound in popliteal space; vessels and nerves exposed in wound. Foreign body retained at back of joint denting the bone	One.
38	Three foreign bodies in joint. Tibia and fibula grooved in front of their articulation	Three foreign body left inside; Five (completed).
51	Foreign body retained in external tuberosity of tibia	Four.

It will be seen that in only one of these failures was a primary operation carried out at an earlier period than three days after injury. In that case (No. 54) a radical operation was impossible, owing to the anatomical relations of the wound.

General Infection of the Joint (25 Cases).

The treatment of these was carried out on the lines laid down above except in four instances in which the joint cavity was exposed by a transverse incision and the knee fixed in a position of flexion. One case only recovered with conservation of the limb, two after amputation (in one case necessary after a secondary operation on the forty-third day to reduce the displacement), and one died.

TABLE IV.—General Outcome of Injuries of this Class.

Total number of cases of general arthritis	25
Missile retained	18
Synovial injury only	1
Bone injury:	
Type 1	13
Type 2	4
Type 3	6
Recovered after arthrotomy	13
Recovered after amputation	6
Died	6

The differential results in relation to the three classified types of bone injury are given in Table II, the outstanding fact being the frequency of general joint infection in the presence of gross comminution of the diaphyses or patella. The one case in which the primary injury was limited to the synovia was No. 40, and has already been described under Group II, A. There were three cases (2, 48 and 50), in which, after an operation had been performed at a casualty clearing station on the day of injury, the wound had been completely sewn up. Case 2 recovered; case 48 died, and case 50 recovered after amputation.

These results emphasize the importance of considering the early treatment of those cases in which severe comminution of bone is present. As stated above, it would seem that an excision of the joint undertaken within twenty-four hours of injury would be the method offering the greatest hope of success.

The results of the examples of primary excision of the wound and resuture in the presence of bone injury, without drainage of any kind, especially as the exact

nature of the primary operation is unknown, are too few to dogmatize upon; but I think some drain should be left in these cases for a few days, so that any infection left after the operation may have a better chance of remaining localized.

Amputations.

Amputation was carried out in ten cases, four of which subsequently died. It is generally a difficult matter, in dealing with these injuries, to determine the time at which conservative measures should be cast on one side and the member removed. In the presence of infection, in addition to gross bone injury or serious lesions of the soft parts, the problem is fairly simple. In other instances the degree and progression of toxæmia are usually the determinant factors. That satisfactory results are usually obtained when little or no bone injury is present is shown by the following table:

TABLE V.—Number of Cases of Each Kind of Primary Articular Injury Ultimately Needing Amputation.

Group II.	Nature of Injury.	Amputation.	Deaths after Amputation.
Class A	(No bony injury present)	1	1
Class B	Gross comminution of epiphyses	2	3
Class B 2	Fissure of diaphysis	1	0
Class B 3	"Punch" wounds and grooves of cancellous bone	2	0

The actual conditions for which amputation was performed in this series were:

Septicaemia	...	8
Secondary haemorrhage	...	1
Gangrene after ligature of the popliteal artery	...	1

The septicaemia or toxæmia was in all cases of streptococcal origin; the micro organism was only isolated from the blood in four instances. The cases so treated were Nos. 25 (5), 27 (5), 29 (10), 38 (53), 40 (40), 48 (24), 49 (15), 50 (16), 51 (29), and 56 (60); the figure in brackets after each case number gives the period in days after the injury at which amputation was carried out.

Death took place in cases 25, 29, 40, and 48, and was due to septicaemia in two instances, secondary haemorrhage in one, and tetanus in one.

Deaths.

The fatal cases were six in number—namely, cases 24 (22), 25 (6), 29 (18), 40 (45), 47 (7), and 48 (28); the figures in brackets give the number of days elapsing between the primary injury and death.

Severe bone injury (Type 1) was present in	3
Fissuring of the bone (Type 2)	2
A large exposure of the synovia, with bone injury	1

Four of these cases were submitted to amputation before death. Case 24 had previously had the other leg cut off for haemorrhage and fracture and died a few hours after a secondary haemorrhage from the popliteal artery on the side of the knee injury. In Case 47 the joint had been laid open and the knee put up flexed, and when the measure adopted failed to check the advance of toxæmia, the patient was not in a position to stand further operation.

SUMMARY AND CONCLUSIONS.

In dealing with wounds of the knee-joint the natural defensive powers of the part against infection should be borne in mind. To obtain fair play for the defence should be the aim of surgical procedures adopted. Primary prophylactic (that is, within twenty-four hours of injury) operations should be radical, and secondary operations undertaken on account of progressing infection, should, short of amputation, be planned on conservative lines.

The expectant treatment of wounds of the knee-joint is only justifiable in the case of typical perforating injuries due to a rifle bullet.

All wounds of the joint caused by shell fragments or distorted bullets should be considered as primarily infected.

The primary prophylactic treatment should consist in the removal of any foreign bodies present and in the excision of the whole wound track at the earliest possible

time after injury. Any delay beyond twenty-four hours will entail failure in a certain proportion of the cases.

The results at present are particularly bad in cases in which gross comminution of the diaphyses is present. A primary excision or erosion of the joint (within twenty-four hours) would probably improve the results in such instances by preventing the development of entomyelitis.

Repeated aspiration of the joint and the intra-articular injection of any of the antiseptics in common use are calculated to prejudice the natural defence.

It is safest to leave some drainage along the wound track after operation for a few days, certainly when bone injury is present. Any infection then left may become localized in the same way as occurs in the case of the peritoneum. A gauze wick makes a satisfactory form of drain.

Immobilization of the joint during all critical periods is essential. An interrupted plaster-of-Paris splint affords the best means of effecting this.

When general infection of the joint has taken place treatment by fixation, lateral arthrotony, and immunization gives the best chance of saving the limb. Secondary abscesses are to be expected, and should be evacuated after their complete development. Neither cross section and flexion of the joint nor secondary excision of the knee are sound procedures.

I am indebted to Lieutenant-Colonel S. G. Butler, D.S.O., R.A.M.C., for permission to publish these notes and to Captain A. B. Le Mesurier, R.A.M.C., for much help in the treatment and recording of many of the cases.

ON THE TREATMENT OF CERTAIN SELECTED CASES OF SEPTIC ARTHRITIS OF THE KNEE.

By CAPTAIN W. RANKIN, R.A.M.C.(T.C.).

MEDICAL OFFICER IN CHARGE OF SURGICAL DIVISION,
No. 1 GENERAL HOSPITAL, B.E.F.

THE septic knee-joint still presents one of the most difficult problems in surgery. Opinion has not crystallized as to the proper line of treatment. (1) Early "prophylactic" excision, and (2) amputation, have been strongly advocated, but in view of clinical experience the first method is not justifiable, whilst the second is a frank admission of failure to deal with the condition. It is not justifiable to do an early excision within twenty-four to forty-eight hours after the injury as a routine method of treatment, since experience at the base definitely shows that a certain proportion of cases recover after a localized suppuration within the joint, and even after a generalized infection with pus formation.

Rest, fixation, lavage, antiseptic injections, serums, etc., all have their functions and scope within the first week or ten days after injury, and if they fail, then further treatment is required.

As regards amputation, it is admitted that in some very acute infections early amputation is the only hope of saving life. If a conservative line of treatment be pursued, and the joint kept rigidly fixed whilst local incisions, irrigations, etc., are used, then the best one can expect as to an end result, after many weeks or months, is a fibro-osseous union where one has no control over the amount of bone and fibrous tissue. All this time absorption is going on, the cartilages are eroding, the ligaments are being broken down, and the patient is at any moment liable to septic venous thrombosis with embolism, and few will escape without periarticular thigh and calf abscesses.

These complications are the inevitable result of lack of drainage in the presence of pyogenic organisms, and it is clear the whole problem of getting a case free from these complications is one of drainage. If one starts, then, from this basis, that the best one can offer such a case after a dangerous illness is a fibro-osseous union between the eroded bone ends and that the joint is almost inevitably lost, then the problem becomes simpler.

Delay in amputating, septic absorption, multiple septic emboli, were responsible for so many deaths in the early part of the war that it had become a working rule with many surgeons that the safest, quickest, cleanest method of dealing with a limb where the posterior pouches of the knee-joint are involved is amputation; thus life is saved at the expense of a limb with least bother to all concerned. Probably it is true this working rule holds good for the majority of cases, but, however perfect artificial limbs may be, and however cleverly used, it is difficult to believe that a stiff rigid leg, even a few inches short, where the hip and ankle-joints are normal is not infinitely superior and preferable to them; and though the cases are long and tedious and trying, yet the end result is worth having if the patient is satisfied and has a good useful limb in a few years. The problem, then, is: (1) To select suitable cases. (2) To drain completely at the earliest moment after one is satisfied that the joint is lost. (3) To get the sepsis overcome. (4) To get firm union of broad bony surfaces. It resolves itself, therefore, into doing an excision of the knee-joint in two stages in suitable cases.

The Suitable Case.

1. The patient must be young; certainly under 30 years, probably best not more than 25 years of age.
2. The favourable cases are lightly built men with small bones and without great muscular development. Fat and flabby cases are unsuitable.
3. The past history as regards general health must be good.
4. Courage and cheerfulness and a strong desire to keep the limb are most important factors. Querulousness and want of interest as to whether the leg stays on or not are contraindications.

The Local Damage must be Within Limits.

1. If the infection be an extremely virulent one then even immediate amputation may fail to save life, and no temporizing dare to be tried in this type of case.
2. If the bony damage is great, if the head of the tibia especially be shattered, then probably amputation is the best line of treatment. Further contraindications are (a) doubt as to the condition of the main nerves to the leg (the ankle action must be perfect to commence with, and be kept good all through the illness); (b) the presence of other serious gunshot wounds.

Taking these points into consideration, and offering unsuitable cases an early amputation as the best and surest treatment for their condition, there still remain many cases, boys with trivial injuries, where amputation seems a catastrophe, and for those cases one must try and get a better result.

It can be done. Time alone can settle whether it is worth doing, whether the end result is a comfortable limb or not. Certain it is that the patient is satisfied with the early result, and this more than anything else impels me to record experience and treatment of these cases.

The Joint is Lost.

1. From the clinical symptoms, the temperature, the pulse-rate, the nature of the discharge, and the general condition afford indications. Tenderness and oedema are sufficient guides; there is no need for definite periarticular abscess formation to prove that the joint is lost, and delay may mean danger of septicaemia and pyaemia, even after the joint has been laid open.

2. A pathological report on an examination of fluid withdrawn from the joint is a most valuable aid, but inasmuch as there is a percentage of cases which recover, even after the pathologist gives a grave prognosis, the clinical symptoms must remain the chief guide. The greatest value is as a stimulus against too great delay in operating in those cases in which the clinical symptoms lack definition and make one hesitate.

Procedure when Drainage is Necessary.

The septic knee-joint cannot be drained. When one considers the pouches, the ligaments, the spaces beneath the cartilages, this is obvious; therefore complete exposure of the surfaces which constitutes the joint must be obtained, and all abscesses which have resulted from leakage through synovial pouches must be freely opened.

This can be done by means of a Ω -shaped incision carried through the quadriceps tendon, by removal of the

semilunar cartilages, by section of the lateral and crucial ligaments so as to make it possible absolutely to dislocate the tibia from the femur and freely expose the posterior wall of the joint (Fig. 1).

FIG. 1.—Line of incision.

The pocket behind the external tuberosity of the head of the tibia is the guide to calf infection, and, usually, the upper and inner limit of the subcrureus pouch to the thigh periarticular infections. Calf abscesses are opened after getting a guide from a pair of forceps passed down the track from the knee. The thigh abscesses present no difficulty.

When this large surface is exposed one is satisfied that what was once a knee-joint is now a completely drained surface. Anything short of this is tinkering.

Experience has shown that the subsynovial tissue, probably as the result of lymphatic infection, tends to swell enormously, and therefore, as a point in technique, it is worth while spending a little time in excising the synovia, at any rate that of the subcrureus pouch.

Preference is given to the incision across the quadriceps tendon, as this allows of the patella being turned down, and gives better access to the pouch.

The patella is left in the meanwhile so as to keep the skin from shrinking, and a few incisions made into the prepatellar bursa help to keep that from becoming distended. No important structures are cut through in this procedure, very little blood is lost, and the operation is one which as a rule does not cause the patient much shock. It is, on the contrary, usually followed by immediate and great relief. Drainage being thus complete, if osteomyelitis and thrombosis have not already set in as the result of bad judgement and delay in operating, the case should naturally tend to settle down, if no further pocketing of pus be allowed.

The surfaces are kept apart by means of a special splint shown in Fig. 2. It was found that patients could lie for

FIG. 2.—Splint applied.

weeks quite comfortably in this position of abduction and rotation outwards of the thigh.

The apparatus was made of wood and perforated zinc, padded with gamgee tissue, but the idea of the splint is passed on to orthopaedic experts for improvement as the position is undoubtedly a good one for the treatment of such cases.

The "abscess" being now thoroughly laid open and the part put at rest it remains to overcome the surface sepsis.

This has not been found easy; cases did badly under "continuous irrigation," and the best results were got, up till lately, with alternated moist carbolic (1 in 40) and spirit dressings, changed once in twenty-four or forty-eight hours. More frequent changing is not practicable, as the dressing is too painful, and the first few dressings require an anaesthetic. After periods varying from three weeks to three months there results a fine clean granulating surface, and after the temperature has been normal for two to three weeks and the general condition of the

patient is obviously improved, one may proceed to the excision.

Whilst up till lately it has been clear that the progress towards an aseptic granulating surface has been more a result of the *vis medicatrix naturae* than the action of the antiseptics applied, it is almost certain that the Carrel method of treatment would be an immense improvement on that formerly used (there has not been an opportunity of making the trial yet), as, in addition to being a less painful dressing, it would hasten the time at which the second part of the operation could be done before contractures have been established.

The last two cases have at this stage been treated with Morison's B.I.P. paste. With perhaps one exception, no previous case has shown in the general and local improvement so rapid an overcoming of the septic process. These dressings did not require changing more than once in four to five days and have been the least painful of all to change, so that there are now at our disposal two greatly improved dressings for this stage, and one can promise the patient and oneself fewer and not very painful dressings and a much shorter period of waiting till the leg is straightened.

Excision.

The excision of the bone ends and the fixation of the limb on a splint which will allow the broad bony surfaces to lie in good apposition need no detailed description. One must cut one's coat to the cloth; provided that there is no rapid overstretching of the popliteal structures and no tension left in the space, then one has taken away sufficient bone without sacrificing any unnecessarily (Fig. 3). The guide is the circulation in the foot and

FIG. 3.—Folded layers of gamgee tissue to elevate heel and produce slight hyperextension at joint level.

toes, and proper attention must be paid to alignment of the middle line of the thigh and the tibial ridge, and an endeavour made to get just a shade of hyperextension. Each case is a separate effort requiring individual treatment, but these are the points to be kept before one.

There is always a certain amount of shock, and the patient's general condition must be good before the operation, but little blood need be lost if a flat tourniquet be used and if the leg be bandaged firmly into its splint before the tourniquet is removed. It is usually unnecessary to tie any bleeding vessels, but the bandaging must be firm over a good pad of gamgee tissue.

An average shortening of 2 to 2½ in. can be obtained even with cases where the excision has to be delayed for some months, but this can be improved on greatly if the Carrel and Morison methods fulfil their promise and one has no troublesome contractures of the soft parts to deal with.

The cases are therefore tedious and trying, and require much patient nursing. They should only be undertaken where there is a likelihood that the case can remain in the same hands till bony union has taken place. To pass such cases on at an earlier stage than this is not fair to any one.

The treatment is therefore one best suited for the base.

RESULTS.

Two cases were done in the summer of 1915. Both went to England with good bony union.

Twenty-seven cases were attempted from summer, 1916, to spring, 1917. Of these, 13 have been sent to England with good union, 3 are almost ready to proceed, 8 died, 3 were in the end amputated (all three lived and were transferred to England well).

Of the cases which died, one was a fulminating case and died in forty-eight hours after admission, one died of

perforating gastric ulcer, 2 died of complicating chest conditions (these four cases should not have been attempted), 4 cases died of pyaemia—the result of hesitation and delay in doing the first part of the operation.

Most of these cases were undertaken during the great rush when all the staff were working under great pressure, and the results must be judged accordingly.

Viewing the matter in the light of the experience gained and the conclusions drawn in this paper, I do not see why the mortality after this operation in selected cases should surpass that of amputation as a routine treatment, and some of the results obtained seemed so excellent that the procedure deserves further trial.

The average duration in hospital before complete drainage was ten days. The average period before excision was sixty days. Six weeks after that most of the cases were ready to go to England. The average stay in hospital was thus about four months.

I desire to express my thanks to Lieut.-Colonel E. C. Hayes, R.A.M.C., for permission to publish these notes, and for his encouragement; to Captain Lazarus-Barlow, R.A.M.C., for his valued co-operation in the examination of the fluids taken from the joints; and above all to the nursing staff, the theatre sisters, and the colleagues associated with me in the treatment and care of these cases.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE DETECTION OF DEAFNESS.

IN the JOURNAL of August 25th, p. 252, I see a suggestion by Dr. Eyre as to the detection of deafness, which I must frankly say I do not understand. Is it intended to convey that because a man hears words whispered six or eight inches from his better ear that he is therefore not "hard of hearing"? If this be not implied, what is the point of the memorandum?

The question as to the detection of deafness is by no means simple, even for the expert. Roughly, the class of cases in which malingering may be suspected falls under three categories:

1. Simulation of one-sided deafness.
2. Exaggeration of deafness which is actually present.
3. Simulation of complete deafness.

As the various methods employed for the detection of simulation are discussed in textbooks, I shall merely refer to those which seem to me most useful. Where the patient states that one ear is quite deaf, this may be verified or the reverse by connecting his ears with the mouths of two observers by means of speaking tubes. Each whispers words into his mouthpiece, and the malingerer will probably soon give himself away by repeating those spoken into the deaf ear. The same result may be attained by the employment of a binaural stethoscope with one limb occluded.

Exaggeration of deafness which is actually present is much more difficult to discover, and even the expert will find such cases difficult. Repeated tests, used at intervals, together with weighing the objective appearances and data derived from the history and comparing them with previous experience, afford the best prospect of success.

These, however, will not assist us very much where complete bilateral deafness is simulated. It has been suggested to try the effect of a loud voice to waken the patient from sleep, while it has also been proposed to employ anaesthetics, but the latter requires the assent of the patient. In such instances I see no method available excepting that of espionage, and if possible inquiry directed to those who have known the patient.

It is, of course, very important that injustice should be excluded, and for this reason it is desirable to impress upon those who examine that the tests employed should not be liable to fallacy.

In examining soldiers it will often be found that an inaccurate statement is made from carelessness, but without any intention to deceive. Thus, if the tuning-fork be applied to the middle line of the head, we shall often be told that the fork is perceived only in the better hearing

ear, even if the deafness be not due to involvement of the nerve apparatus. Again, we shall be told that if the good ear be closed the fork is no longer heard. I have seen this so frequently among men who obviously had no desire to impose upon me that I have ceased to attach any value to the phenomenon.

P. McBRIDE, M.D.,

Consulting Surgeon, Ear and Throat Department,
Royal Infirmary, Edinburgh.

RUPTURE OF UTERUS: RECOVERY.

ALTHOUGH annular rupture of the uterus in the neighbourhood of the cervico-vaginal attachment is sufficiently common to be described in the larger textbooks, the following case presents unusual features which make it worth placing on record:

I was called to the patient late in the evening of April 3rd by a midwife on account of prolonged labour. The os was fully dilated, the membranes unruptured, and the head and umbilical cord presenting.

On rupturing the membranes the cord immediately prolapsed outside the vulva; no pulsation was to be felt. The head was above the brim of the pelvis, which was flattened in its antero-posterior diameter. I performed internal version without difficulty, but was unable to extract the after-coming head; in endeavouring to extract, I caused a fracture of the cervical vertebrae and pulled away the body of the child, leaving the head behind and tearing through the cord in the process. The head being well pressed down by the midwife, I then perforated and extracted with difficulty with a cranioclast.

On examining again after delivery of the head I found an annular rupture of the uterus extending completely round the cervico-vaginal attachment except for a thin pedicle by which the uterus was still attached posteriorly; the placenta had escaped into the abdominal cavity. I seized the uterus with a pair of craniotomy forceps, placing one blade in the cavity and the other outside, and dragged it down through the vagina; the remaining attachment I ligatured as high up as possible, and so completed the separation of the uterus.

The pulse by this time was very bad, but there were no signs of haemorrhage, and, the nearest hospital being fourteen miles away, I decided to adopt an expectant attitude, and in the meanwhile applied restoratives.

On the following day the pulse was stronger, rate 132, and I considered her fit to stand laparotomy. Mr. Washbourn, of Gloucester, saw her with me in the afternoon, and opened the abdomen in the middle line below the umbilicus. A moderate amount of blood clot was removed from the pelvis, but there was no recent haemorrhage; the placenta was found in the neighbourhood of the splenic flexure; the abdomen was quickly closed with the exception of a gauze drain into the pelvis.

A week later, the discharge through the wound having become purulent, I sent her into Gloucester Infirmary, where she was treated by douches, etc., and discharged five weeks later with the wound closed.

The patient had been married four years, and had had two previous pregnancies; the first terminated in the expulsion of a stillborn fetus (described by the midwife as "macerated") at the eighth month; the second in a miscarriage at the seventh week. The uterus was normal to the naked eye, and it was impossible to determine where the rupture had commenced.

I am indebted to the courtesy of Mr. Washbourn in publishing the later part of this case.

Cinderford.

GEORGE F. RIGDEN, M.B., B.S.Lond.

A HUGE MESENTERIC CYST IN A YOUNG MARRIED WOMAN.

MESENTERIC cysts are extremely rare things. The subject of the instance here reported is a young married woman, aged 25. She had never been pregnant, and menstruation had been recurring regularly, although during the last eighteen months the periodic loss had been increased somewhat. She had never experienced pain in connexion with menstruation. Five weeks before coming under my care she began to experience some difficulty in fastening her corsets, and this increased so rapidly that during the last three weeks she had to dispense with them altogether; this increase in size was her sole trouble. On cross-questioning, she stated that her "stomach" had always, as long as she could remember, been rather big.

I found the abdomen very prominent; it was occupied by a swelling which extended from the pelvis to 5 in. above the umbilicus. The percussion note over the tumour was everywhere dull. The right flank was resonant; the left was dull; fluctuation was readily elicited. By vaginal examination I found the cervix located anteriorly towards the right side. I could not differentiate

the body of the uterus. In the left pelvis was felt a portion of the abdominal swelling. The base of the swelling in the pelvis was traversed by a peculiar network of fine fibrous bands, and this physical sign made me think the tumour might be in the substance of the broad ligament.

Operation.—I experienced the greatest difficulty in gaining an entrance into the peritoneal cavity, as the tumour was in the lower third of the abdomen incorporated with the anterior abdominal wall. On attempting to find the peritoneal cavity the tumour, unfortunately, ruptured, and from it flowed about a gallon and a half of haemo-biliary-looking fluid. When I eventually reached the greatly curtailed peritoneal sac I found the small intestine everywhere incorporated with the sac of the original tumour. The sac was stitched to the abdominal wall and drained. None of the pelvic organs could be felt, a fact which made me think the swelling must have started in the lowermost part of the mesentery and have developed extensively both up into the abdomen and down into the pelvis.

JAMES OLIVER, M.D., F.R.S. Edin.

RESUSCITATION OF THE NEW-BORN INFANT BY HEART MASSAGE AND OXYGEN.

On several occasions I have found it possible to resuscitate a baby by heart massage in the manner suggested by Dr. Fisher in the *BRITISH MEDICAL JOURNAL* of August 18th, p. 215.

Recently, after a prolonged labour due to disproportion between the head and the pelvis in a primipara, aged 39, the child was delivered by forceps at 9 p.m. The cord had been pressed upon high up, and was round the child's neck. The child was white and limp and the heart had ceased to beat. Massage of the heart for some minutes started it beating, and artificial respiration was begun. At 9.30 p.m., though the heart was beating feebly and artificial respiration was continued, the child did not breathe naturally. Oxygen was then given in a very gentle stream whilst continuing respiration artificially for more than an hour, when the child began to breathe feebly by itself; he was still cold. Wrapped up in wool and warmed blankets, surrounded by hot-water bottles, he was placed near a fire, and oxygen slowly and continuously administered. By 4 a.m. the child became warm, and at 9.30 a.m., twelve hours after birth, oxygen was discontinued, and he was bathed and dressed. On visiting him later in the day I found him very yellow and his lips much swollen. He is now doing well.

ARTHUR DE VINE.

A CASE OF PNEUMOCOCCAL PERITONITIS WITH ACUTE GASTRIC DILATATION.

THE rarity of the condition may make it worth while to record the following case:

Pte. W., aged 20, Middlesex Regiment, was admitted on February 12th with a temperature of 104° F., under Dr. Syrett. Pneumonia was diagnosed, first on the left and later on the right side also. The attack was severe, the temperature reaching 104° on February 13th, 15th, and 20th; then the temperature fell gradually to 99° on February 22nd. The pulse also fell from 132 to 98. Hope was raised that the patient was recovering, but vomiting of dark bilious fluid began, and at 6.30 p.m. the same day, in consultation, we found peritonitis and tympanites reaching up to the fifth rib. Obstruction was diagnosed. It was considered that the patient was too weak for operation. The vomiting became more copious and urgent. At 11.45 a.m. on February 23rd the patient died.

A *post-mortem* examination was made four hours later, and so much did the stomach fill the abdomen that at first no other organ could be seen save the liver. The fundus was pushed up to the fifth rib, and the greater curvature reached to within an inch of the pubis. The transverse colon was in the true pelvis, where the ileum lay quite empty and collapsed. The colon was contracted also. The duodenum was stretched to a diameter of 2½ to 3 inches. The duodeno-jejunal flexure was normal in size, and must have been pressed on by the mesentery, for gas seemed to be entering merely from manipulation during examination.

There were no adhesions or acute obstructions. There were, however, several flakes of lymph, yellowish-white in colour, thready and toughish, as is characteristic of pneumococcal empyema. These came down on to the smaller curvature and fundus from the diaphragm. It would therefore appear that the stomach was paralysed by toxæmia acting on its nervous plexuses, and that distension occurred, which further caused pressure on the terminal part of the duodenum.

Those practitioners who are robbed, as it were, of their pneumonia cases just as they are on the turn for recovery will naturally feel interested in the question of the frequency of such a condition. Messrs. Rowlands and Turner (*Jacobson's Operations of Surgery*) quote 91 cases of this rare disease, all children under fifteen. In 30 cases the peritonitis was secondary to a lesion elsewhere, especially in the lungs and pleura. Primary infections had occurred in the throat or ear in several cases. Of gastric dilatation of the stomach Osler, in *Principles and Practice of Medicine*, quotes 102 cases. Of these, 42 followed operations with general anaesthesia. The next largest group occurs in the course of severe diseases or during convalescence. It is noteworthy also that we had an outbreak of pneumonia, sore throats, and cerebro-spinal meningitis going on during February, when this case occurred, and our past experience leads us to expect appendicitis with this group in the spring season.

This case is published by permission of Lieut. Colonel J. Kearney, R.A.M.C., S.M.O. Harwich Garrison.

E. F. SYRETT, M.D.

W. L. CHRISTIE, Captain R.A.M.C.,
M.D., F.R.C.S. Eng.

GLUE FOR APPLYING EXTENSION IN FRACTURES.

In a useful note on the application of glue extension (Sinclair's method) in the *JOURNAL* of July 14th (p. 60) I notice that there is no reference to the use of spirit glue for similar purposes.

In my experience Heusner's glue is as efficient as that described; and, further, it has the advantage for those who do not need to use the application frequently that it is always ready for use as stored; moreover, it is an excellent and cheap substitute for mastisol, and is a much better adhesive than any form of collodion when used for applying gauze to the skin.

I referred to the preparation in an article published in the *BRITISH MEDICAL JOURNAL* last year ("A simple system of skeleton splinting"), and also in the *British Journal of Surgery* for July (p. 70). The composition I have used is as follows:

Methylated spirit	50 c.cm.
Benzine	25 c.cm.
Resin (commercial)	50 grams.
Venice turpentine	5 grams.

I consider the preparation to be of sufficient value to the practical surgeon to deserve attention.

C. MAX PAGE,

— Field Ambulance, B.E.F. Captain R.A.M.C. (S.R.)

Reviens.

THE THYROID GLAND.

As a record of eminently original investigations extending over fourteen years, and advancing surely step by step to the full understanding and successful treatment of a group of conditions that are as distressful as they are widely spread, Major McCARRISON'S book upon *The Thyroid Gland in Health and Disease* must rank as the foremost medical publication of the year. It is an outstanding example of that best and most characteristic form of British pathology, the pathology of the active practitioner whose clinical studies and clinical opportunities impel him to investigate, and, with Edward Jenner, to apply the results of his inquiries to the treatment and control of the condition investigated. It promises well for the continued advance of British medicine that in our generation McCARRISON does not by any means stand alone, although it may safely be said that there is no one who has pursued his inquiries under greater difficulties or in greater isolation, and therefore with all the greater credit.

The story is fascinating, and as, with characteristic modesty, in the book before us it is implied rather than definitely stated, and then in the appendix rather than in

¹ *The Thyroid Gland in Health and Disease*. By Robert McCARRISON, M.D. (R.U.I.), D.Sc. Belf., F.R.C.P. Lond., Lauréat de l'Académie de Médecine, Paris; Major Indian Medical Service. London: Baillière, Tindall, and Cox. 1917. (Crown 8vo. pp. 286, with numerous illustrations. 12s. 6d.)

the substance of the work, it may be timely to give it in outline.

In 1902, as a member of the Indian Medical Service, McCarrison, a young Belfast graduate, found himself stationed at the very confines of the empire, high up in the Himalayas, in the Gilgit valley and Chitral district, some 5,000 to 8,000 feet above sea level. Here, as in so many alpine districts, endemic goitre and cretinism were rife. In some of the villages the disease was so common that it was difficult to find a man, woman, or child unaffected. That there is an intimate relationship between water supply and goitre development had already been clearly determined, although what was the nature of the relation was the subject of numerous hypotheses. Bircher and others in Switzerland had shown that the replacement of the water supply from wells by a pipe supply taken from a running stream had resulted in the complete disappearance of goitres among the children in certain villages. Charlton had demonstrated clearly that the incidence of goitre on the island of Montreal depended on the water supply; villages that received their water from the St. Lawrence river or from deep wells were unaffected; those that had shallow wells, presumably receiving surface water, were extensively involved. This pointed to some microbic agency, but not to infection of the ordinary type, since the goitres disappeared when the individuals removed to other non-goitrous areas or altered their water supply.

Before. After.

FIG. 1.—Photographs of a patient suffering from goitre, to illustrate the effect of treatment by thymol. Circumference of neck before treatment, 40½ centimetres; after treatment, 37 centimetres.

McCarrison's first published observation (1906) was upon the incidence of goitre in relation to water supply. He reported upon conditions in a series of seven villages situated one below the other along the course of a stream. He found that the percentage of infected houses, of affected individuals in these houses, and in the total population of the villages affected, showed a steady increase in passing down the valley, there being a slight drop in the incidence in the fourth village, situated below the junction of a tributary diluting the main stream with a purer supply. These observations received interesting confirmation some three years later, when Marine and Lenhart, and after them Gaylord, made parallel observations upon artificially bred trout contained in a succession of wooden troughs, the water from the upper passing to the next lower in the series. That trout may suffer from goitre had already been noted in Germany.

These observations led McCarrison to make investigations (1906-10) upon the goitrogenous constituent of the contaminated water. These were conducted upon non-goitrous men, newcomers to the Gilgit valley. A notoriously goitre-producing water was passed through a Berkefeld filter, and the residue given in milk once or twice a day over periods varying from thirty to fifty-five days. Of thirty-six individuals so treated ten developed a noticeable enlargement of the thyroid, five a transitory swelling only; whereas, of thirty-one individuals who consumed the same suspended matter after it had been boiled, none showed any enlargement.

Here, again, later American observations are curiously parallel. In 1912 Gaylord showed that by scraping the inner surface of wooden tanks in which fish with endemic goitre had been confined, and administering the scrapings to dogs and rats, he could produce the goitrous state in these; he showed also that the agent is destroyed by boiling.

McCarrison's conclusion gained was that the water was probably contaminated with the excreta of the goitrous individuals. To test this during the next two years a series of experiments was conducted upon non-goitrous goats, with the result that 9 out of 20 goats, fed for periods of from 60 to 108 days on a water grossly contaminated with the faeces of goitrous persons, developed goitrous changes—a finding, it may be added, which was confirmed by Sasaki at Heidelberg in 1913. McCarrison obtained yet more definite results in 1913 by employing white rats. With these animals, whether they were fed with an emulsion of the faeces of goitrous persons, or with the filtrate from the same, or with food fouled with their own excrement, 100 per cent. developed goitre. Control rats protected against faecal contamination showed no change.

With this McCarrison had arrived at a clear understanding of the nature of endemic goitre: it arises from faecal contamination of the water or food supply. That ordinary faecal matter will induce the thyroid enlargement indicates the absence of any strictly specific agency: that the filtrate from faecal emulsions will induce the condition indicates that we deal either with a toxæmia or the action of a filterable virus. In favour of the former view are the facts that the condition, if not too long established, disappears when the contaminated water is no longer used, as well as McCarrison's further observation—that the vast majority of goitres are sterile, yielding no cultures. Nevertheless, he

Before. After.

FIG. 2.—Photographs of a patient suffering from goitre, to illustrate the effect of vaccine treatment of goitre (autogenous coli vaccine).

now proceeded to inquire which orders of intestinal bacteria are effective in causing thyroid enlargement, and found that anaërobic bacteria from the faeces are particularly active in inducing the condition. What is more, by feeding female rats with anaërobic cultures obtained from the faeces of goitrous persons, of 19 offspring 10 showed definite congenital goitre, and 11 equally definite parathyroid disease (haemorrhage and fibrosis). The majority of these were born dead. Feeding faecal filtrate from goitrous persons to goitrous female white rats throughout pregnancy (that is, by setting up a milder toxæmia), of 17 young 3 were cretins, 7 had congenital goitre, and the remainder were apparently normal.*

Professor W. H. Thomson of New York had for years emphasized the part played by intestinal toxæmia in the production of Graves's disease, and had recommended treatment by intestinal antiseptics. Farrant also had independently demonstrated the action of the *B. diphtheriae* and other pathogenic organisms in causing thyroid hyperplasia. To my knowledge, no one before McCarrison had attempted the experimental production of cretinism.†

It is evident that from a very early date McCarrison perceived the direction in which his inquiries were leading him; in 1906 he was already treating these goitrous cases with thymol, beta naphthol, and salol, and this with marked success, a success obtained also by Messerli of Lausanne in 1916. In 1913 he similarly reduced the incidence of goitre in a large school in the Himalayas by the chemical purification of the water supply, with the result that the percentage of goitre among the boys was

* It deserves note that in 1903, as Major McCarrison points out, Sajous had called attention to the thyroid hyperplasia induced by bacterial toxins.

† Some of the points noted in the preceding paragraph are illustrated in the photographs reproduced in the BRITISH MEDICAL JOURNAL of July 28th, p. 112.

reduced by one-half. Since then, to reduce the intestinal toxæmia, he has employed with good effect "soured milk," prepared from a good strain of the *B. bulgaricus*, and of late has obtained excellent results, in cases not too far advanced, by employing mixed autogenous vaccines of intestinal organisms, administered in increasing doses, varying from 150 million to 1,000 million of the organisms. *Staphylococcus* vaccines have proved efficacious, as has also a vaccine prepared from a spore-bearing organism, gained from a goitrous horse. It is interesting to note (p. 110) that, despite these good results, Major McCarrison still believes that there must exist a specific intestinal organism of endemic goitre. He explains the action of these other vaccines by holding that they aid the disappearance of secondary infections, and so, by relieving the thyroid of its abnormal burden, enable it to combat successfully the specific toxin. But to repeat, all his evidence points to an intestinal toxæmia rather than to a specific infection. So also, as he points out, do certain remarkable cases of Sir Arbuthnot Lane's, in which the goitre has disappeared after an operation to remove intestinal stasis.

This is not a criticism of Major McCarrison's book upon the thyroid gland; it is a *précis* of the part he has played in the recent developments of our knowledge of thyroid disease. Space forbids a fuller description of his studies upon cretinism, the tetanic form of cretinism, parathyroid disease, and Graves's disease. It is only necessary to state that after this intensive study of the last fourteen years he writes magisterially concerning both the physiology and the pathology of the thyroid system, and to add that the work appears in admirable form, with full justice done to the many most effective illustrations.

NOTES ON BOOKS.

DR. A. T. NANKIVELL has written a useful little book on *Health in Camp*,¹ founded on a series of Chadwick Trust Lectures he gave in 1914. It is addressed to soldiers, boy scouts, and caravanners, is thoroughly practical, and avoids unnecessary technical language. The need for such instruction is well expressed by Sir Shirley Murphy in a short introduction. In civilized communities, he says, so much is done for the inhabitants by municipal authorities that when they are converted into soldiers they must be taught how to adapt their habits and utilize their opportunities so as to provide themselves with a healthy environment, for which they have previously largely relied upon municipal aid. The book contains chapters on the choice of a site and the laying out of a camp, the erection of huts, tents, and bivouacs, the provision of surface drainage, latrines, and washing and cooking places. Other chapters deal with refuse disposal, including that from horse lines, and with insect life and minor ailments in camp; there is an excellent chapter on the need and method of day-to-day supervision, and a good index.

Human Physiology,² by Professor STILES, of Harvard University, is a textbook designed for the pupils of high schools and colleges who wish to learn the elements of the science. The author has endeavoured to present the accepted facts to his readers concisely, avoiding contentious matter and mere theory. Details and experimental proofs are not discussed, and conflicts of evidence are indicated rather than described; there are a few diagrams to help out the text. Professor Stiles writes clearly, and gives an excellent yet simple summary of human physiology, so far as that ideal can be attained without reference to practical work in the physiological laboratory. Yet one may feel inclined to ask how far even an embryo physiologist can be brought up with success upon a purely predigested pabulum, however attractive the form in which it is presented.

THE TREATMENT OF CORNEAL ULCER.

DR. TERSON points out to us that in our review of his *Ophthalmologie du Médecin Praticien* we have been guilty of an oversight in stating that for the treatment of corneal ulcers the use of atropine and of a bandage are not mentioned. Dr. Terson does suggest that a light bandage should be used to

support a warm fomentation. This treatment does not recommend itself to us; the use of a moderately firm bandage and a dry pad, which is not mentioned, seems to be the sheet anchor of the medical man who is called in to give first aid to a case of corneal ulcer. As regards atropine, Dr. Terson warns the practitioner against its use. Had he said that care should be taken in employing atropine in the case of elderly persons we should agree with him; but the general condemnation of the drug deprives the patient of the most essential element in the therapy of this dangerous condition. We cannot agree with Dr. Terson that atropine should be reserved for cases complicated with iritis. Atropine is useful to "splint" the eye, and to prevent the formation of posterior synechiae.

MEDICAL AND SURGICAL APPLIANCES.

The Repair of Rubber Operating Gloves.

DR. N. I. SPRIGGS, F.R.C.S., Captain R.A.M.C.(T.) (Leicester), is led by the publication of the note under this heading in the *JOURNAL* of August 18th, p. 228, to call attention to a letter he published in the *Lancet* of March 31st. Being struck by the number of punctured and torn rubber gloves which were discarded, he devised an electric vulcanizer, which he hoped might be put on the market. Technical difficulties intervened, and it was found more convenient to get the firm of W. and A. Bates, Rubber Mills, Leicester, to undertake the repairs with the apparatus. Dr. Spriggs considers that perhaps £10 a year or more could be saved on each 100 beds in a hospital in this way. The repairs thus effected have the following advantages over patches simply stuck on with rubber solution: (1) The patches are so small as to be almost impalpable; (2) they do not come off, even after repeated sterilizations; (3) a new finger can be put on a glove: for instance, the right forefinger of a glove is often lacerated badly and needs renewal; (4) a long slit can be repaired, or a new wrist affixed, or two lacerated gloves made up into one good one. Dr. Spriggs adds that gloves are often sterilized at too high a temperature when done in a high-pressure steam sterilizer, the temperature in which may reach 270° F., which is practically a vulcanizing temperature, so that the gloves become brittle and sticky, and perish very soon. A lower temperature should be used for a longer time, but he is unable to find a sterilizer specially suitable for gloves. When once the "nature" is out of the rubber of course no kind of repairs are of any value, but slits and holes accidentally made in good rubber gloves can be repaired.

Messrs. Bates inform us that they have entered into a contract with the Admiralty for repairing gloves, and that they also repair gloves for some military and civil hospitals. The number of gloves repaired for three large general civil hospitals and three military hospitals in twelve months was 6,042. The cost of the repairs was £98 6s. 3d. They estimate the cost of this number of new gloves at £302 2s.

A Hammock Suspension for Fractures.

A "hammock suspension" for fractures, the invention of Miss Gasetti of Paris, has, it is stated, been extensively employed in France under the authority of the Government, and is now being introduced into this country. It is used in connexion with fractures of the femur and humerus, and the special merits claimed by the inventor are improvement in the comfort of the patient, and that by its use the nursing of these cases is rendered comparatively easy. Four wooden uprights are attached—one to each bed-post—and these are connected above by two longitudinal pieces. On the longitudinal pieces and immediately above the patient's limb rest two transverse pieces, which serve as the basis for the attachment of pulleys, by which the lower limb secured in a splint is suspended from the bed. The splint used for a fractured femur resembles the "Thomas" bed splint, without, however, the dorsal portion of the ring. By means of a transverse piece at the end of the bed attachment is given to a pulley, on which a weight plays for purposes of extension. This pulley can be set at varying angles of abduction. In the case of a fractured humerus, by means of a system of pulleys, not only can extension be made on the arm, but the limb can be suspended from the bed as well. In this way it is claimed the upper limb can, without displacement, accommodate itself to varying positions of the patient's trunk. The appliance has nothing to recommend it over the more simple Thomas bed splint and the abduction splint of Colonel Sir Robert Jones as used at the military orthopaedic hospitals in this country and in British military hospitals abroad for simple or compound fractures of the femur.

SATURDAY, SEPTEMBER 1st, 1917.

THE ARMY MEDICAL SERVICE INQUIRY.

THE Committee of Inquiry into the Army Medical Service, promised by the Under Secretary of State for War during the discussion on the Army Medical Vote on August 14th, has now been constituted and is at once going to France. Its reference has been enlarged, inasmuch as it is directed to inquire into various matters connected with the personnel and administration of the Army Medical Services in France, and afterwards to carry out similar investigations in the United Kingdom. The chairman is a general officer who has held many important military commands in peace and war, and the secretary, Dr. Christopherson, is well known for his research work, and as an administrator in the Sudan. Of the six medical members of the Committee five are members of one or more of the statutory committees recognized under the Medical Service Acts—the Central Medical War Committee, the Committee of Reference of the Royal Colleges in England, or the Scottish Medical Service Emergency Committee. The Committee, with the exception of the chairman, thus consists of civilian practitioners, of whom one holds a temporary commission R.A.M.C. The Committee starts with the advantage of a knowledge of the situation at home as it affects the civil population; but, as will be seen from a note in the SUPPLEMENT, the Central Medical War Committee desires that its chairman should be added.

It will be well to recall certain events preceding the appointment of the Committee. The first was the letter addressed by the Central Medical War Committee to the Secretary of State for War on August 3rd, informing him that that Committee was of opinion that no more medical men could be called upon to take commissions in the R.A.M.C. without seriously endangering the supply of doctors for the treatment of the civil community, and that further depletion could only be effected on the responsibility of the Government after carefully comparing the military with the civil needs. The second circumstance was that a series of questions were addressed to the War Office in the House of Commons which brought to the notice of that assembly current allegations to the effect that the number of medical officers claimed by the military authorities in France and at home was in excess of requirements, and that many of those abroad had little or nothing to do, while at the same time the civil population was suffering from a deficiency of doctors. The third circumstance was that during the debate the question of the status of the Army Medical Service in relation to the Army Council was raised.

The appointment of Sir Francis Howard to be chairman of the Committee which has proceeded to France serves to bring prominently to mind the fact that the Army Medical Service is a subordinate branch of the Adjutant-General's Department. This is often forgotten. The Army Medical Service does, in fact, enjoy a large measure of autonomy, and in practice makes provision for the prevention of disease in the armies, and for the evacuation and treatment of wounded and sick, subject to various limitations of

authority relating especially to the provision of transport and supplies other than drugs, instruments, and certain specifically medical stores. The system can be made to give excellent results, as we have seen in the British armies in France, but it may lead to very unfortunate results, as the story of the Mesopotamian Expedition proves. The subordination to the Adjutant-General's department affects not only the army medical branch at home but extends all through, so that the principal medical officer of an army corps is officially related to the general officer in command, not directly, but through the Adjutant-General of the corps, and for certain purposes through the Quartermaster-General. This is a survival into the widely different conditions of to-day of the opinion of Lord Wolseley, founded on experience of minor expeditions, that the proper place for the principal medical officer of a force was at the base. The opinion was never sound; it is now antiquated, and has, we believe, been abandoned by all successful generals.

The Commission appointed to apply the lessons of the South African war heard weighty evidence in favour of making the Director-General, A.M.S., a member of the Army Council; this would have implied that the department of the Director-General, A.M.S., would have been autonomous in the same sense as those of the Adjutant-General and the Quartermaster-General, and would have been dependent or subordinate to neither. The Commission did not accept the advice, but Lord Esher last February admitted that this was a mistake; he wrote: "No one except Sir Alfred Keogh could envisage the Royal Army Medical Corps other than an important but small branch of the 'services' attached to an army in the field. It was not realized that to keep a force in the field was at least as vital a necessity as to recruit it. September, 1914, swept away this illusion—but the mischief was done . . . Certainly the control of the Adjutant-General's branch over the Royal Army Medical Corps was and is responsible not only for the early failure to grip the medical factors of this war, but for the hampering conditions under which Sir Alfred Keogh has worked. His triumphs and those of the Royal Army Medical Corps have been achieved in spite of obstacles that the subordination of science to ignorance, of elasticity to military discipline, explains but cannot justify." Lord Esher went on to appeal to the Secretary of State for War to "strengthen the Army Council by placing upon it the D.G.M.S., and to free from the control of a purely military officer (admirable as is Sir N. Macready in the sphere congenial to him) a body of men mostly volunteers from highly trained professions, and dealing with technical difficulties altogether outside the orbit of vision in which the soldier pure and simple habitually moves. Thus would the work of Sir Alfred Keogh be happily recognized to the infinite advantage of our sick and wounded to-day and to-morrow."

Whether the Committee which has now gone to France will go into this large question of administration we do not know, but its reference appears to be wide enough to justify it in making recommendations on this head. We are aware that there are weighty objections to making so radical a change at this stage of the war, since the existing plan has been made to work, but we have to look to the future, and it is to be hoped that the Committee will take the opportunity of looking into the matter and putting its opinion on record.

But the Committee will probably consider that the main duty of urgent importance before it is to inquire into the manner in which the personnel at the disposal of the Army Medical Department is now utilized and

whether economy in the number of medical officers employed in France and in the United Kingdom can be effected without loss of efficiency. The urgency of this question is well known both to the profession and the War Office.

HARVEY ON THE USE OF THE CIRCULATION.

PROFESSOR JOHN G. CURTIS, of Columbia University, who died in September, 1913, left for publication a book on the work of William Harvey.¹ The task of preparing the manuscript for the press was entrusted by him to his colleague, Professor Frederick S. Lee. The work, which is based on a lecture delivered before the Johns Hopkins Hospital Historical Club at Baltimore in 1907, is an attempt to define Harvey's position in the evolution of physiological thought. Dr. Curtis devoted much labour to the endeavour to reach an understanding of the doctrines of the ancient physiologists which to the modern mind are so mysterious, and his critical discussion of their meaning gives his work a special value to the student of the history of medicine.

It may come as a surprise to those who have not made a first-hand study of Harvey to find that the man who brought about one of the most far-reaching revolutions in science did not, like Bacon, regard the ancients with contempt, but held them in great reverence. He was steeped in their speculations; and even in his old age he is reported to have told John Aubrey to "goe to the fountain head and read Aristotle, Cicero, Avicenna." The gossip Aubrey is not always a trustworthy authority, and one may excusably feel a doubt as to Harvey's alleged recommendation of Cicero as a "fountain head" in physiology or medicine. His respect for Aristotle, however, is conspicuous in his own writings, and the Greek outlook on nature by direct observation and experiment was in harmony with the temper of his own mind. To him the first object of search was the fact, and to critics who like Riolanus attacked his discovery his reply was that objectors "plainly ought to inquire as to its existence before inquiring why it exists: for from the facts which meet us in the circulation regarded as existing its uses and objects are to be sought."

In the absence of positive knowledge Harvey was driven to speculation. In seeking for the uses of the circulation, he was led to consider the feeding of the tissues, the significance of respiration, the cause of the heart-beat, the relative importance of the heart and blood in the economy, the body heat and its source and the seat of the soul. But before the discovery of oxygen no satisfactory explanation was to be found. Aristotle taught that animal heat, which is indispensable to life and to the working of the soul, is kept from burning away too fast by the cooling influence of the inspired air, and following the "master of those who know" Harvey concluded that "it is the nature of animals to need cooling on account of the firing of the soul within the heart." Harvey's private lecture notes of 1616 show that he accepted the ancient view of the importance of the heat of animals, and he spoke of respiration in the language of Hippocrates.

In connexion with the subject of breathing Dr. Curtis made some instructive remarks on the meaning attached by the ancients to those puzzling words

"pneuma," "spiritus," and "anima," which for many centuries were put to such various uses by physicians, philosophers, alchemists, and theologians. In the fourth and fifth centuries before Christ it was believed that something derived from the outer air is in the vessels which also contain the blood. To denote this substance the Greeks used the word "pneuma," the fundamental meaning of which seems to have been "air in motion." The word, however, came to have other significations, such as the breath, the wind, the air, and things which in modern speech are called gas, vapour, steam, exhalation, or emanation. The equivalent Latin word is "spiritus," and in English "spirits" was used to express various meanings of "pneuma." As to the nature of the animal spirits, an expression which only survives in colloquial English, Curtis says the adjective "animal" is used in its original sense of "pertaining to the soul"; for this the Latin word is "anima," the Greek "psyche." "Psychical spirits" would be the best rendering into the English of to-day of either the original Greek "pneuma psychicon" or the Latin "spiritus animalis." These "animal spirits" or spirits of the soul were not peculiar to man but were also possessed by his "poor relations," and even, according to Aristotle, in a lower grade by plants. For Galen the animal spirits were the first instrument of the soul, the medium of sensation and volition; they had their origin in the ventricles of the brain, from which they were supplied, to the spinal cord and nerves, the fibres of which were believed to consist of tubes in which the subtle spirits were contained. The animal spirits were sustained by three kinds of respiration—pulmonary, cutaneous, and cerebral. Curtis says that a modern physiologist might see in the vital spirits a dim foreshadowing of oxyhaemoglobin, and in the operation of the animal spirits a plainer foreshadowing of what is now called nerve impulse.

To Aristotle are largely due Harvey's references to the heart as the central source of indispensable vital heat and to aliment perfected in the heart, and his blending of psychological doctrines with his teaching as to the movement of the blood. Even in his old age the English physiologist wrote that the authority of the Greek philosopher had always such weight with him that he never thought of differing from him inconsiderately. But he was a man whose independence of mind could not allow him *jurare in verba magistri*, and, in opposition to Aristotle, who gave the chief place in the economy to the heart, he transferred that primacy to the blood, which he came to regard as the very seat of the soul. To this doctrine, which sounds so strange to a modern biologist, Curtis devotes a chapter in which he shows that for Harvey the word "soul" did not mean as it did for Hamlet, the immortal part of man, but was simply the equivalent of "psyche" or "anima." Harvey's views as to the cause of the heart-beat, the venous return, the blood and innate heat, and the relations of his teaching to that of the ancients, are set forth with a great wealth of illustration from the writings of his predecessors. A brief account of his controversies with Scaliger and Fernelius on the subject is given—all now to us "a tale of little meaning, though the words are strong." The book ends with a short chapter dealing with Harvey's parallel between the circulation of the blood and the circulation of the heavenly bodies.

In some thirty pages at the end of his book Dr. Curtis indicates the sources of his account of the doctrines of the ancients and of Harvey, and the list is proof of the thoroughness with which the subject was studied. The book is illustrated with a portrait

¹ *Harvey's Views on the Use of the Circulation of the Blood.* By John G. Curtis, M.D., LL.D., formerly Professor of Physiology in Columbia University in the City of New York. New York: Columbia University Press. (Post 8vo, pp. 204; 4 illustrations. 5s. 6d. net.)

of Harvey, a transcript of a passage of his *Prelectiones*, which gives a terrifying presentment of his almost undecipherable handwriting, a photograph of the title-page of the editio princeps of the treatise *De Motu Cordis*, and a picture of the Anatomical Theatre at Padua, which is still one of the sights of the famous University where Harvey studied. The room, which is of modest proportions, has an amphitheatre for the audience around a small central oval pit where the lecturer must have stood close beside his "subject." One can picture the young English student leaning on one of the rails of the narrow tiers watching with close attention every step in the demonstration of his master, Fabricius ab Aquapendente.

"HOW WE ARE TO BE GOVERNED."

A LETTER with the title at the head of this paragraph appeared in the *Times* of August 28th, and though the writer signs himself "An Outside Observer" he is evidently well acquainted with the conduct of public affairs both in Parliament and in Government offices. He begins by the assumption that the Government we shall have after the war will be neither the Government we had before the war nor that evolved during the war, and he lays it down as axiomatic that the functions of a central government are twofold—control and administration. Some departments are concerned almost wholly with control, others are almost wholly executive, but both in the past have been similarly administered. At the head was a politician who only accidentally had any familiarity with the class of business he was set to manage. In the Admiralty and the War Office there were boards of experts, the Sea Lords and the Army Council. In all other departments the permanent secretary was frankly and undisguisedly the head. While the ability, the familiarity with precedents, and the devotion to public interest of the secretariats were all unquestioned, their education was purely literary, and their training made a man an official, not a man accustomed to make rapid decisions on practical affairs. The system might perhaps be described as bureaucracy tempered by questions in the House of Commons. Under the pressure of the war we have seen men of affairs with special practical knowledge placed at the head of several of the great departments of State, but even if this were the best possible solution it is not likely to be continued after the war, when the politician will again take care to come into his own and we shall again have the round man in a square hole, and vice versa. The writer goes on to contend that the country cannot afford after the war to shed from the Government its experts and business men, nor can it be permanently governed by the crowd of *ad hoc* committees called into existence by the emergency of the war. His suggestion seems to be that a Government department should be conducted more or less on the principle of a public company, with a board of expert directors and a managing director to carry out its behests. Lord Rosebery some years ago wrote a paper or made a speech in which he seemed to suggest that the Board of Admiralty should be taken as a model for other departments. The War Office has the Army Council, and the Secretary of State for India has a council, and it can hardly be, the writer from whom we are quoting adds, "that a council in departments such as the Local Government Board, the Board of Trade, and the Board of Agriculture would be a useless excrescence. No department can contain all knowledge within its four walls. The innumerable special committees that have been appointed during the war seem to prove two things: that outside knowledge and experience are of real use, and that men whose services command a high price in the outside market are glad to give

those services to the country gratuitously." It is hoped that when and if a Ministry of Health is constituted the principle of a consultative board of experts will be embodied. Meanwhile the reconstitution of the Ministry of National Service affords an opportunity of putting the principle at once into force. The extent of the work the Ministry is to undertake does not seem yet to be settled, but it has been reconstituted largely to take over recruiting and establish a satisfactory system for the medical examination of recruits. A great deal of the criticism of the working of army medical recruiting during the last six months owed such force as it possessed to what was regarded as the defective system of notification of recruits the medical examining boards were expected to carry out, and to the character of some of the instructions and circular letters issued to them in the Commands. We believe that the new Minister of National Service would do well to institute at once a medical advisory or consultative committee to deal with the principles by which he should be guided in issuing general instructions, and to advise him on any regulations or instructions he may find it necessary to issue from time to time. Such a body should have permanence, and could easily be constituted from members of the Committee of Reference, the Central Medical War Committee, and the Scottish Medical Service Emergency Committee, with, possibly, the addition of medical representatives of certain Government departments concerned. In addition to the matters already mentioned, a consultative committee constituted as suggested would be well qualified to advise the Minister as to the constitution of the local medical recruiting boards, and, with the assistance of the experience of the Local Medical War Committees, to ensure that the members of the local boards were chosen from among members of the medical profession in the various localities able and willing to undertake the responsible work of the medical examination of recruits, so as to ensure recognition of the true physical condition of each man and appropriate classification.

THE ORDER OF THE BRITISH EMPIRE.

A NUMBER of medical men and women are included in the first list of the new Order of the British Empire, which has been instituted for the special purpose of recognizing services to the empire in connexion with the war. Honorary Lieut.-Colonel Edward Stewart, R.A.M.C., Medical Assessor to the British Red Cross Commission in France, is created a Knight Commander. Dr. Louisa Garrett Anderson, organizer of the first hospital run by women at the front; Lady Florence Elizabeth Barrett, M.D., who has rendered valuable service in connexion with the British Red Cross Society; Lieut.-Colonel Jay Gould, I.M.S., Commissioner of the British Red Cross in Mesopotamia; Dr. Thomas Wheeler Hart, County Director of the British Red Cross Society, East Lancashire; Dr. Flora Murray, medical officer in charge of the Endell Street Hospital; Dr. Mary Scharlieb, who has done valuable social work in connexion with the war; and Dr. Alexandra Mary Chalmers Watson, chief controller of the Women's Army Auxiliary Corps, have been made Commanders of the Order. Dr. Wilfred Balgarnie, Assistant County Director of the British Red Cross Society for Hampshire, is made an Officer of the Order; while the first Members of the Order include Dr. S. J. O. Dickens, Commandant and Medical Officer of the British Red Cross Society for Sussex; and Dr. G. C. Franklin, medical officer in charge of the Hawkstone Red Cross Hospital, Fareham, who was President of the British Medical Association in 1905, when it held its annual meeting at Leicester. A remarkable feature of this honours list is the fact that the son and daughter of Dr. Elizabeth Garrett Anderson, the doyen among women medical practitioners, both receive high awards: Mr. Alan Garrett Anderson, lately vice-chairman of the Wheat Commission, and now Controller at the Admiralty, being

appointed Knight Commander, and Dr. Louisa Garrett Anderson a Commander. This family record becomes the more remarkable by the circumstance that Mrs. Chalmers Watson, also a Commander, is a cousin of Dr. Louisa Garrett Anderson and sister of Sir Eric Geddes, K.C.B., First Lord of the Admiralty, and a Knight Grand Cross of the new Order, and of Sir Auckland Campbell Geddes, K.C.B., Minister of National Service, who is a member of the medical profession and Professor of Anatomy in McGill University. Many other workers on behalf of the Red Cross and of various special agencies for the relief of suffering receive recognition in the first list of the Order, among whom we may mention Mr. Arthur Stanley, Chairman of the Joint Committee of the British Red Cross Society and the Order of St. John of Jerusalem; Mr. W. H. Goschen, Chairman of King George V Hospital; and the matrons of St. Bartholomew's, St. Thomas's, Guy's, and the London hospitals. It is announced that lists for India and the Dominions, as well as for the civil, military, and naval services, will appear at a later date. On behalf of the medical profession we congratulate those of its members who have been honoured by inclusion in the first Order of chivalry open to both sexes, and instituted for the sole purpose of rewarding zeal and merit in the national service during war time.

THE CAMPAIGN AGAINST VENEREAL DISEASE IN GERMANY.

At a recent meeting of military surgeons, Ministerial-direktor Kirchner¹ read a paper on new ways in the campaign against infectious venereal diseases. This title was not happily chosen, for he seems to have given a gloomy retrospect of legislative fiascos rather than new and definite schemes for the future. But even his retrospect is interesting, and his tale of laws framed only to be broken is certainly instructive. At the outbreak of the war, the decree of 1907, dealing with prostitution, was suspended by the military authorities, who reverted to the legislative measures of 1898. These measures did not prove satisfactory, and the war had not lasted long before supplementary regulations were demanded. It was urged in some quarters that brothels and their patrons should be shielded from the rigors of the law, while the Conservatives and the Centre hesitated thus to license licentiousness. The nature of some of the suggestions made is shown by the demand that every person should be liable to compulsory examination, that the infected should be isolated compulsorily till they were no longer infectious, and that professional secrecy, as between patient and physician, should not be permitted. Kirchner considered that Neisser's programme—commonly known as Neisser's testament—framed shortly before his death, went too far. Neisser's wish to penalize sexual intercourse by persons knowing that they were infected would lead, in Kirchner's opinion, to blackmailing, the breaking up of family life, and to suicide. Kirchner's attitude to the problems of venereal disease is evidently well epitomized in one of his sentences: "Certainly more must not be done than is absolutely necessary."

URINARY EXCRETION OF SALICYLATES.

HANZLIK, SCOTT, AND THORBURN² have investigated the quantitative excretion of salicyl in acute rheumatism, in non-rheumatic patients, and in normal persons, in the attempt to throw light on the mechanism of the therapeutic effect of salicylates in acute rheumatism. About 20 c.cm. of a 10 per cent. solution of sodium salicylate was given hourly until toxic symptoms appeared; this on an average was after a quantity equalling 13.8 grams of salicylic acid had been taken. The fluid intake was

meanwhile kept as constant as possible, 100 c.cm. an hour, until toxic symptoms appeared, and then 200 c.cm. hourly until salicyl disappeared from the urine, a period of three or four days, when the experiment was finished. It was found that in acute rheumatism the total excretion (60 per cent.) of salicyl was about 15 per cent. less than in normal persons (75 per cent.), and that this difference was greatest during the first ten or twenty hours after administration of the salicylate. Further, the concentration of salicyl both in the blood and in the urine of rheumatic patients when manifesting toxic symptoms was less than in normal persons in the same circumstances. The difference in the urinary excretion is not due to diuresis, or to retention and vicarious excretion, for example, by the skin, but to destruction of salicyl which is more marked in a febrile rheumatic than in a normal person. The excretion of salicyl was also investigated in the following four diseases: Chronic alcoholism, chronic morphinism, febrile tuberculosis, and lessened renal efficiency, and the amount of salicyl was found to be diminished to about the same extent as in acute rheumatism, thus indicating increased oxidation or destruction in these conditions. An important practical point was also noticed in this investigation and confirmed by the observation of some hundreds of cases in the Lakeside and City Hospitals of Cleveland—namely, that the addition of sodium bicarbonate does not modify or prevent toxic symptoms from the administration of salicylates. The late Dr. David Lees strongly insisted on the importance of giving double the quantity of alkali with salicylates in order to prevent salicylism, and British physicians have largely adopted this owing either to the influence of the old alkaline treatment or to the more modern fear of acidosis. It is conceivable that rheumatism does not react to salicylates in America in quite the same way as in this country, for in the earlier editions of Osler's *Medicine*, before the author left Baltimore, English students were surprised to read that the only effect of salicylates on acute rheumatism was the relief of pain. Although this explanation may appear rather doubtful, it is difficult from experience to believe that Lees's treatment is futile. The addition of sodium bicarbonate did not influence the rate of the urinary excretion of salicyl.

PSEUDO-APPENDICITIS ZOOPARASITARIA.

In 1899 Professor G. F. Still found oxyurides in the vermiform appendices of children under the age of 12 years, and considered that catarrhal changes might thus be induced. Two years later Metchnikoff reported three cases of appendicitis associated with the presence of *Ascaris lumbricoides*, which he thought prepared the way for the bacteria responsible for the inflammation. Since then numerous writers have maintained the view that there is a causal relation between worms and appendicitis, and others have opposed it. In an elaborate paper on the pathology of worm infection of the vermiform appendix, based on examination of 103 appendices removed by operation at Freiburg i. Breisgau, and of 23 appendices from the *post-mortem* room at Edinburgh, Dr. Y. Matsuoka¹ concludes that worms are neither directly or indirectly the cause of acute or of chronic appendicitis either in children or in adults. Among the 103 operation cases worms or their ova were found in 48, or in nearly every second appendix, and in 45 instances (25 containing worms) the appendix was normal. In these 25 cases there were clinical symptoms suggesting chronic appendicitis—namely, chronic pains and slight tenderness on pressure in the ileo-caecal region, but fever was absent or there was only a very slight rise of temperature. This condition is more than twice as common in females as in males, and can be recognized by the presence of worms or their ova

in the faeces. The proper treatment is removal of the worms, not of the appendix. Aschoff, under whom Matsuoka worked, came to similar conclusions, and called the affection appendicopathia, but as this name does not entirely exclude the possibility of an inflammatory origin for the symptoms the title pseudo-appendicitis zooparasitaria is preferred by Matsuoka.

TUBERCULIN IN CANCER.

At a meeting of the Swedish Förening for the Invärtes Medicin, Dr. I. Holmgren¹ gave an account of his experiments with tuberculin in several cases of cancer. While he was medical superintendent of the St. Göran Hospital he had occasion to make necropsies on between three and four thousand tuberculous subjects, and was struck by the complete absence of malignant growths. It was therefore possible, he thought, that the tuberculous toxins might possess an inhibitive action on the growth of cancer cells. He found that the subjects of cancer were astonishingly tolerant of tuberculin, and, after he had experimented some time with comparatively small doses, he realized that much larger doses could be tolerated without any reaction. Indeed, in some cases he gave 100 mg. subcutaneously at the first injection. Of the fifty-two patients thus treated the majority did not react at all. There was no rise of temperature or general symptoms, and in 88 per cent. there was no rise of temperature above 38° C. (100.4° F.). In the few cases in which a febrile reaction occurred it lasted only a few hours. Ultimately Dr. Holmgren came to regard tolerance for tuberculin as such a characteristic feature of cancer that he employed it in the differential diagnosis between cancer of the stomach and simple, chronic, gastric ulcer. He did not consider the absence of a reaction to tuberculin simply to be the outcome of the patient's cachectic condition, for these patients showed great tuberculin tolerance long before the stage of cachexia was reached. He was reserved in his estimate of the effect of the tuberculin on the course of the disease, which in every case was unsuited for operative or radium treatment. In two cases the disease ran a strikingly slow course, showing practically no progress during an observation period of more than a year. Several other patients felt much better for the injections and felt worse when they were interrupted.

PULSUS ALTERNANS AND DIGITALIS.

The bad reputation of digitalis in cases of heart disease showing the pulsus alternans is unmerited, and is explained by Windle² as due to the common error of regarding as the pulsus alternans irregularities in the force of the pulse due to premature or extrasystoles succeeding each normal beat, or to auricular fibrillation. Extrasystolic bigeminy not uncommonly ensues in patients fully under the influence of digitalis, and hence the misconception that digitalis has the power of causing the pulsus alternans. From observation of the effects of digitalis on the pulse of patients with pulsus alternans Windle finds that this form of irregularity is not increased; on the contrary, it not infrequently disappears temporarily while the symptoms are improved in all respects, even though there may be a coincident rise in the arterial blood pressure. The last circumstance is at first sight surprising, for, as the pulsus alternans is invariably the expression of an overtaxed heart, it might be expected to become more pronounced with increased peripheral resistance. It appears, however, that the pulsus alternans signifies disproportion between the contractile power of the heart and the rate at which it is beating; and that, in fact, the most powerful of the factors influencing the persistence, increase, decrease, or

abolition of the pulsus alternans is the rate of the heart; thus in the same patient it is the rule to find alternation increased with a rise and diminished with a fall in the pulse-rate. Digitalis abolishes pulsus alternans only when it slows the pulse, and the rate of the pulse at which alternation ceases is usually the normal, but exceptionally this form of irregularity persists when the rate is somewhat below normal, and is a very ominous sign, for since alternation points to disproportion between the strength and rate of the heart, it follows that the slower the rate of a pulsus alternans the greater is the cardiac exhaustion. A slow pulsus alternans—namely, about the normal rate—is only seen in senile cardio-vascular degeneration, and it is a particularly bad prognostic to find a persistent alternation when digitalis has slowed the pulse down to 70 to 80 per minute.

A FARM COLONY FOR TUBERCULOUS SOLDIERS.

The good work done during the war by the Young Men's Christian Association in the provision of huts and in other ways is well known and has received recognition from many general officers and many medical officers in the field. It is now making an interesting experiment in the establishment of a farm colony to provide a home and industrial training for discharged soldiers suffering from tuberculosis in its early stages. The farm comprises thirty acres of land, arable and pasture, with good buildings and a farmhouse. A number of huts, specially designed for the purpose and each containing two beds, have been erected on a sheltered and wooded portion of the estate for the accommodation of patients. The farm is in the neighbourhood of Poole, Dorsetshire, its soil is gravel and sand, and water is laid on. The colonists are to stay on the farm for periods of not less than three months, determined by the committee on the recommendation of its medical advisers. Patients are put to such useful work as they are capable of performing with benefit to their health, and it is hoped by a system of graduated labour to restore them to their full working capacity. Men who on their admission are unfitted for active exercise begin by making mops, mats, and so on; next they walk from one to six miles a day next they do light gardening work and attend to poultry and rabbits; then they begin to use a small shovel, then to dig broken ground and mow grass, and finally do such heavy work as trenching, mixing concrete, felling trees, and other work on the farm. The honorary medical adviser in London of the committee managing the colony is Dr. T. D. Acland, and it is intended that patients shall, as a rule, only be admitted after examination by him. Dr. Hyla Greves of Bournemouth is acting as consulting physician, and Dr. Small of Poole as visiting physician. The institution is under the general direction of a lady commandant, there is a resident nurse, and an ex-sergeant-major of artillery with two years' experience of Frimley sanatorium will be in charge of the men for discipline and instruction. If this experiment succeeds, as we hope it may, it is the intention of the Y.M.C.A. to form other colonies on similar lines. At a meeting of the National Council of Young Men's Christian Associations at the central office, Tottenham Court Road, on Tuesday next, at 7.30 p.m., Dr. Halliday Sutherland will give an address on consumption, its cause and cure, illustrated by a cinematograph film.

DR. MADISON TAYLOR has tried his hand at drawing up a register for the collection of trustworthy vital statistics. It contains provisions and directions for recording personal and family characteristics, and histories of birth, growth, health, disease, etc., with blanks for such supplemental data as photographs, clinical and dental records. The volume also includes articles on the child as a problem to parents, the building of a citizen, environment and inherited tendencies, personal hygiene, age and age values, and the development of the mind. The publishers are the F. A. Davis Company, Philadelphia.

THE WAR.

AN AMBULANCE IN REST.

BY

CAPTAIN ANDREW MACPHAIL,
CANADIAN ARMY MEDICAL CORPS.

In the Canadian Corps there is a saying that the life of a soldier is a long Newfoundland rest, which means that one stops work and begins again. A field ambulance never rests, unless it be by accident. Such an accident befell one August. There is now no harm in speaking of it, since it happened so long ago, and the phenomenon is of so rare an occurrence.

For more than eleven months we had been in the Ypres salient, still a salient, but now happily turned in the opposite direction. We left it without regret, since that particular part of Belgium is not calculated to inspire much enthusiasm as a place of residence. During that year the only rest was a change of work. But now the corps was on the move, and there was a chance that some particular unit might remain in a sheltered nook whilst the army flowed by.

To move an army corps is a simple, but precise, affair. The corps proceeds by divisions; divisions proceed by brigades; brigades by battalions. Accessory services all have their place—artillery, sappers, pioneers, ambulances, and train. These various units at the initiation of the movement may be scattered over the countryside. They can be set in motion at a word as easily as if they were railway trains. The trick is to start each unit at the proper time, so that it will fall into the column at the appointed place. The capacity of roads is limited. Roads make detours. They cross and converge. It demands nice calculation to set the whole corps going upon a main line of communication fifty miles long.

A unit of the Second Division, for example, may find itself well to the rear when the movement from the front begins. It must move out to give place to an incoming unit, and there it must wait until the First Division has passed, and its own division has come down. On the first day a unit moves out by a short march into an open country. On the second day it makes a long march, and waits in billets until the appointed time. That was the happy chance which befell the Nth Field Ambulance.

The short march brought us from Belgium into France. Every mile the scene of desolation faded. The hops were now hanging in festoons, the buds well formed, and the clear ground between the rows of high poles seemed like an endless bower. By noon we came into a large farm which was at our disposal. The farmer made us welcome. He was a grave, handsome man, and very rich. He owned 110 acres of land. He had two daughters and seven grandchildren in his house. His only son went to the war two years previously, and had not been heard of since.

Next day came the long march. At least it was considered long, and no secret was made of the opinion. By this time the Ambulance was a veteran one, and not a man fell out. It was a holiday for these young Canadians, walking through the pleasant country. War alone could have created such a day upon which peaceable and peace-loving boys should march on the business of war through villages which bore the names of Quæstraete, Oxelaire, Bavinchove, Noordpeene, Belembers, Volkerinchove, Boolezele.

Boolezele was the place of rest. To every man in this particular unit Boolezele will always be remembered as the place "where our caravan has rested." The day's march and the quiet interval that followed was an interlude between Ypres and the Somme. We had moved out at 7 in the morning. Rain threatened, but the farmer assured us that the "barometer was good." In every French farmhouse is a barometer, and it is consulted as if it were an oracle. The farmer was right. The morning continued cool and cloudy until we climbed the shoulder of Mt. Cassels. Then the sun came out, and we had brilliant August weather, with the light in a strong blaze travelling from field to field. France disclosed to us all its dignity, beauty, and richness in dainty châteaux half hidden in wooded parks, in massive buildings set in large undulating

and hedged fields. For such a treasure-house France may well fight.

Towards evening we gained the summit of a hill through a long avenue of trees. The land fell away to the left. A yellow road led down the slope and upward again towards the west. Red roofs were shining in the sun across the valley, and a single spire lifted itself to the sky. The Quartermaster came riding back and met us at this spot. His young face shone as if he had seen an angel. He had been into the promised land. This was our place of rest, and he was to be our guide.

The march was twenty miles. We had been in the saddle, or afoot, for nine hours, and there was yet something to be done before we sought our billets. But we had done it so often that now it did itself. Wagons were parked and off-loaded. The fifty horses were put on their lines. Hospital tents were erected. The cooks were at work. The men were fed and the details of the camp were left to those who were responsible for them.

There was dinner at an estaminet—hot soles from the sea in a rich, brown sauce, two pairs of portly ducks, yards of crisp bread, butter fresh from the dairy, and coffee made with a loving hand. The woman served the meal with a light heart. Her husband was *permissionnaire*; he sat in his own kitchen smoking his pipe, and we gave him much respect. A French soldier is sacrosanct in our eyes. We go softly in his house.

We were in civilization once more. Each house stood square on its own bottom. The walls were intact, and true as a plummet could make them. The church had a spire and its windows glowed in the sun. The Place was undefiled by the debris of war. Women walked in the streets, free and unafraid. We spoke with them. Fresh from witnessing the bowed and broken women of Belgium, who creep in the gloom and mire of their ruined homes, or toil in their heavy black fields, these French women seemed to be creatures of life and gaiety; but at a chance word the smile and sparkle would fade. In the presence of unshed tears the conversation died.

The instinct to set up a separate establishment quickly showed itself. There was a desire to withdraw from the common life, and to eat alone. Out of this arose the idea of hospitality to show how well one lived. In a day a society was created. Invitations were issued, and men who had lived in common for nearly two years now found themselves the guests one of another. It happened at times that all ten officers of the unit found themselves under the one roof, as if they were in the common mess again, but it was quite different. They were fellow guests of the one host, and were governed by a new convention.

One who lives in a house of the richer sort quickly imputes to himself the magnificence of the owner, and classes in the little society were created. The Major, whose hospitality rises to genius, had his billet in the house of a woman who was reputed to be very rich, and very religious. The invitation to visit him was quite formal. One is scrupulously careful to present a visitor to the woman of the house, who is the superior host. Then we are in society indeed, and may even be invited to the kitchen. In the present case the kitchen was a room with a roof of glass, which sloped towards the morning sun. Two enormous grape vines entered the room below the roof and spread themselves over the transparent ceiling. The one vine bore red grapes; the other bore white grapes, and the clusters hung in hundreds within the room.

The woman with her tireless old feet ran for a ladder. She climbed the steps, and cut clusters of red and white grapes. She set them forth on the table and placed a bottle of red wine in the midst. Then she proceeded to our entertainment. She told us marvellous things. This war, she said, was in preparation for forty years. When she was a child, living in her father's house, they had a workman who was a prophet. He foretold that she in her time would see great wonders—namely, ships that sail in the air, engines running in the cities, horses sweeping the streets, and a great war. Five years ago she was returning from a pilgrimage at Lourdes. On the way she stopped in Paris at the house of a nephew, who is a physician. One morning as she was taking a little promenade in the streets of Paris she beheld the first three portents. From that day she expected the great war, and it had come. The story was very long and much complicated by extraneous matter, but as the woman spoke very fast and in a shrill voice, and as she lacked many teeth and her mouth

was filled with grape skins, I could not gather all the finer points of her discourse.

We were indebted to a curious chance for a further introduction to the larger society of the town. I was walking in company with my dog, who was of a whimsical type. A woman began to call to him in a peremptory voice. He suppressed his indignation at the familiarity, and followed close with more than usual gravity. As the woman came nearer she discovered that the dog was not hers, but she was careful to explain the source of her error. She had a dog at home like mine, and I must come and see. She did not think it possible that there were two dogs in the world of that breed. As we walked to her house she explained that her dog had come from Lille, and I assured her that I would seek out his relations when we came to that town. Before the visit was at an end, she said that her son was at the Somme, and I assured her that if I met her son I would bring him the news: that his mother had given me a glass of wine; that she had showed me the garden, the pheasants, the rabbits, the ducks, and the two horses. "And do not forget the dog when you come to Lille," she said. "In that way you will find my relations."

One evening the band of the Xth Battalion played in the Place. They played all the Peer Gynt suite, whereby we were given much respect. All Society was there. Each one introduced the friends he had acquired during the day, and so we were established.

The music was for the entertainment of our hosts, and the performance of the pipe-band was received with excessive politeness. An old man with the sad face and homely dress of a peasant was listening with an expression of deep concern and a trace of shame, as if unwittingly he were present at some alien rite. I asked him how he liked the music. "I do not understand it," he said, and with a gesture of self-deprecation he added, "I am afraid the fault is in my ears."

During those few days each officer manifested his especial genius for making himself comfortable in his own way. The adjutant smoked cigars, and heard never a word that was said to him. The Young Major made a methodical acquaintance with every inhabitant of the town. First, he determined the main family lines; then he investigated the collateral branches and ascertained their relationship. He entered into the joys of the young and the sorrows of the old. He visited the sick, and did not complete his ministrations until he was summoned to the convent to consult and advise upon the condition of the *refugiés* who were sheltered within its walls. The Colonel enjoyed himself in his orderly room poring over establishments, writing his war diary, checking nominal rolls, and verifying accounts. The officer with the Italian voice spent whole days visiting the shops to seek out the strange foods which are affected in foreign parts. One captain passed the time with his stethoscope. It was nearly a year since he had sufficient leisure to expend upon a case and examine the patient to his satisfaction. The sounds he heard seemed to give him as much pleasure as if they originated in an old and well-played violin.

When the newness of the situation wore off, the surrounding district afforded fresh interest. To obtain a general view one climbed the church tower. It was a blue, blowy afternoon, following a sunny, showery morning, and earth and sky were at their cleanest and freshest. From this considerable elevation of hill and tower there was much to be seen. To the north—Dunkirk, with a flash of breaking wave in the Channel beyond; Gravelines to the west of that; and Calais itself in a dun cloud away to the south. Two years ago the advanced guard of the enemy was arrested in this very town. The enemy was within actual sight of Calais. That will be for ever a bitter moment in his history.

The village to the north stands upon higher ground, and from its church tower on a clear day the cliffs of England can be seen. The colonel of a battalion which was billeted there showed his solicitude for his officers by allowing them to climb to the steeple and take a look at England when he could not grant them leave.

Best of all we were out of the mud. With the nearness to the coast, the nature of the soil had changed and the roads were crisp with sand. In Belgium the horses slid and slipped over the greasy earth; here their hoofs bit

into the path with a clean, crunching sound. This was riding for pleasure, by curving paths and sunken lanes as beautiful as any in England, where we had once spent nearly five months in training.

By common consent, the most perfect billet of all was in the house of a man named S—. It was a small house, but it stood in the street of the rich. The man himself had been a scrivener or writer to a notary, and by long service his right hand was cramped and distorted. The malady affected his foot as well, but he was a *rentier*; he owned his house and garden, and was a person of much consideration in the community. His sister lived with him, a silent, shy woman, who crept about the silent rooms in silent slippers of cloth.

The spare room was at the back, a little place with a large bed, and a window that looked into the garden toward the east. This garden was a walled court, with pear trees ripening their fruit against the warm walls, and all manner of vegetables growing in the moist shade. In the middle of the court was a bed of flowers, such as blaze with colour in the late August. Beyond all this were the rich fields of France, wooded slopes, and pastures luscious with grass.

The woman had the repute of being a *chef de cuisine*. In the morning she proved that it was so. In the little room that fronts the street a table was spread. There were pears from the garden, an omelette from the clean kitchen, coffee clear as a trickle from a Highland peat bed, milk hot—yet free from scum—little breads of white flour, and butter made whilst the food was preparing.

Meanwhile the battle of the Somme was in progress. Officers were returning who had gone to prepare the way. They furnished us with an estimate of the casualties we should be obliged to care for. They explained the lie of the land—Tara Hill, the Sunken Road, Death Valley, Casualty Corner, Pozières, and Courcellette. They told us what was expected of the Canadian Corps. Our colonel, commonly called "the dear little colonel," missed not a word which would help him in his enterprise, little recking that this was his *coœna suprema*.

That day a motor ambulance went to St. Omer on its usual business; we were to move in the morning. The driver brought back certain things from the market, and there were four persons at table. That evening the old order passed away. Again there were pears from the garden. There was a mackerel—one apiece—cooked as no fish ever had the honour of being cooked, *à la meunière*, as the miller's wife cooks a fish, with brown butter and parsley. There were two young chickens from a near-by farm, and lettuce so living that the leaf complained aloud before it took the oil. Also there was wine of Burgundy and contentment.

In the morning we moved out upon the road at day-break. It was a morning heavy with clouds. The sun leaped up red. A sergeant from New Brunswick uttered the oracle:

Evening red and morning grey
Will bring the traveller on his way,
But evening grey and morning red
Will bring down showers on his head.

We took the road southward by Watten, and as if the portent were not complete, a rainbow raised its arch in the western sky. "A rainbow in the morning is the sailor's warning," the sergeant said. And it fell out as the sergeant had foretold.

ARMY MEDICAL SERVICE.

A COMMITTEE OF INQUIRY.

THE Secretary of State for War has appointed a Committee composed of

Major-General Sir Francis Howard, K.C.B., K.C.M.G. (chairman),
Sir Rickman John Godlee, Bt., K.C.V.O.,
Sir Frederick Taylor, Bt.,
Sir William Watson Cheyne, Bt., K.C.M.G., C.B., M.P.,
Lieut-Colonel H. J. Stiles, M.B., C.M., F.R.C.S.,
Dr. Charles Buttar,
Dr. Norman Walker, and
Dr. J. B. Christopherson, F.R.C.S., F.R.C.P. (secretary),

to proceed at once to France for the purpose of inquiring into various matters connected with the personnel and

administration of the Army Medical Services in that country.

On their return they will carry out similar investigations in the United Kingdom.

Sir Francis Howard, who distinguished himself in the Sudan campaign of 1898 and during the South African war, was Commander-in-Chief of the Western Command in 1905-7, and Inspector of Infantry 1914-15. Sir Rickman Godlee, Sir Frederick Taylor, and Dr. Buttar are members of the Central Medical War Committee, the last named being Chairman of its Executive Committee. Sir Watson Cheyne, who is a consulting surgeon R.N., as well as M.P. for the Universities of Edinburgh and St. Andrews, is a member of the Reference Committee of the Royal Colleges in England, as are also Sir Rickman Godlee and Sir Frederick Taylor. Dr. Norman Walker is convener of the Scottish Medical Service Emergency Committee. Lieut.-Colonel Harold J. Stiles is the well-known Edinburgh surgeon who in addition to other war work is Deputy Inspector of Military Orthopaedics (for Scotland). Dr. Christopherson, the secretary, saw service during the South African war, and is Director of the Khartoum and Omdurman Civil General Hospitals.

VENEREAL DISEASE IN THE AUSTRIAN ARMY.

At a meeting in Lemberg¹ of medical officers serving in the Austrian army, Dr. Moldovan of Vienna gave an account of the measures taken to combat venereal disease in the army in the field. About 4 per cent. of the men were notified yearly to be suffering from venereal disease. The numbers admitted to the central hospitals showed a decrease in gonorrhoea and soft sore, but syphilis was apparently on the increase; 5 per cent. were infected at the front, 20 per cent. on the lines of communication, 75 per cent. outside the sphere of the army. The majority of infections occurred in brothels. The measures taken were personal prophylaxis, sanitary control of prostitutes, and thorough, timely treatment. The sphere for prophylactic treatment was in the interior; it was more difficult at the front. The sanitary control of prostitutes within the army sphere was most vigorously carried out. There were hospitals and out-patient departments for diseases of women, compulsory examination if necessary, and periodical control of prostitutes. Out-patient departments for soldiers suffering from venereal disease were also provided and field brothels, where examination before, and personal prophylaxis after, intercourse were enforced; thoroughness of treatment was guaranteed by collecting the infected soldiers in a big central hospital. In cases of syphilis Wassermann's reaction was used at intervals of three months after discharge, and treatment was renewed when necessary. By timely treatment and the disclosure of concealed cases all plans for wholesale examinations of the soldiers on demobilization would be superfluous. The control of venereal disease was effected through regular, periodical examination by the army medical men, and by eliminating the sources of infection near the front.

Professor Finger of Vienna discussed venereal disease in the interior, and pointed out that as the ordinary methods of superintending prostitution did not fulfil their aims they must be faulty. Only a small number of women were under control, in Berlin only 5,000, while it was estimated that there were 25,000 clandestine prostitutes. Again, the least dangerous were under control; 70 to 75 per cent. were infected with syphilis before they were registered. The most dangerous were the young women, because they were most in demand and were most recently infected. The principles which had proved successful in combating other infectious diseases must be applied to venereal disease—namely, dissemination of knowledge, facilities for treatment, including compulsory treatment, notification of the dangerously infectious and punishing the careless. In 1906 Denmark gave a lead by adopting legislation on these lines. Treatment by quacks must be forbidden, as also the distribution of leaflets on self-treatment and treatment by correspondence. Unrestricted compulsory notification was not advisable because it required such complicated machinery, and because it frightened patients away and favoured blackmailing, but a

system of notification limited to the dangerously infected was required.

Professor Lukasiewicz of Lemberg described the distribution of venereal disease in Galicia before the war and the condition of the East Galician Carpathians, where syphilis had been endemic since the Russian invasion in 1848. The number of patients treated in hospitals in Galicia in 1913 was about 10,000, and the total number of cases might be estimated at 250,000 at least. The war had made this state of affairs worse. The Russian occupation brought an increase of venereal disease. In 1916 the number of women admitted to hospital through the agency of the police was 1,340 as compared with about 100 in peace. Hospitals, out-patient departments, and consulting rooms were established. He insisted on the need for penalizing the spread of infection, of enlightenment by school medical officers, and on the employment of local practitioners for treatment, the control of wet nurses, and compulsory examination of children who were going to be suckled. He also advocated compulsory treatment, prohibition of quackery, a limited system of notification, and extension of the obligation of professional secrecy to every official who had to deal with venereal disease.

HONOURS.

A SUPPLEMENT to the *London Gazette* issued on August 25th contains a further list of awards for conspicuous gallantry and devotion to duty. The names of the following medical officers appear in the first portion of the list:

D.S.O.

Lieut.-Colonel John Smith Purdy, A.A.M.C.

For conspicuous gallantry and devotion to duty. Although continually under shell fire for seven days, he exercised close personal supervision over the evacuation of the wounded, and by his own example of courage and disregard of danger he animated all ranks with a similar attitude of mind. His work during preliminary preparations displayed the same untiring energy and devotion to duty.

Major Rupert Iggulden Furber, A.A.M.C.

For conspicuous gallantry and devotion to duty. He had charge of an advanced dressing station for five days, during which it was under heavy shell fire most of the time. He displayed the greatest ability and devotion to duty in organizing the dressing and evacuation of a large number of the wounded, on several occasions helping to bring them in himself.

Bar to Military Cross.

Temporary Captain Ernest Harrison Griffin, M.C., R.A.M.C.

Military Cross.

Captains A.A.M.C.: Jack Rowland Stanley Cross Beard, Wendell Inglis Clark, Laurence Bedford Elwell, Raphael Leo Kenihan, Keith Shelley Parker, Harold Powell, Fritz Peter Max Solling, Cedric William Whiting.

Temporary Captains R.A.M.C.: Charles James Lodge Patch, Laurence Cecil Sebastian Roche, John Ross, Bernard Charles Tennant, Herbert George Willis.

Temporary Lieutenants R.A.M.C.: George Errington Lloyd, Frank Gordon Fedley, John Edward Sandilands.

MESOPOTAMIA HONOURS.

In a supplement to the *London Gazette* of August 25th are announced the following appointments, promotions, and awards for medical officers in connexion with the military operations in the field in Mesopotamia:

To be C.M.G.

Lieut.-Colonels and Brevet-Colonels: Matthew Henry Gregson Fell, R.A.M.C.; John Macfarlane Sloane, D.S.O., M.B., R.A.M.C.

Temporary Colonels: Charles Neil Campbell Wimberley, M.B., I.M.S.; Walter Holland Ogilvie, M.B., I.M.S.

Lieut.-Colonel Edward Victor Hugo, M.D., F.R.C.S., I.M.S. Temporary Lieut.-Colonel Thomas Percy Legg, M.B., F.R.C.S., R.A.M.C.

To be Brevet Lieut.-Colonels.

Majors: L. J. M. Deas, M.B., F.R.C.S., I.M.S.; J. D. Graham, M.B., I.M.S.; A. W. M. Harvey, M.B., I.M.S.; H. M. H. Melhuish, I.M.S.; T. S. B. Williams, M.B., I.M.S.

To be Brevet Lieut.-Colonels on promotion to rank of Major.

Captains: L. Dunbar, M.B., R.A.M.C.; W. MacNaughtan, M.B., R.A.M.C.; L. H. L. Mackenzie, M.B., I.M.S.

D.S.O.

Acting Colonel Hugh Murray Morton.

Lieut.-Colonels: James Henry Robinson Bond, R.A.M.C.; Edmund Ludlow Perry, I.M.S.; William Arthur Woodside, R.A.M.C.

Major and Brevet Lieut.-Colonel George Browne, M.D., I.M.S. Acting Lieut.-Colonel Edmund Tytler Burke, M.B., R.A.M.C. Temporary Lieut.-Colonel Arthur Brownfield Fry, M.B., I.M.S.

¹ *Deut. med. Woch.*, April 5th, 1917.

Majors: Samuel Robert Godkin, F.R.C.S.I., I.M.S.; Thomas George Ferguson Paterson, M.B., I.M.S.

Captains: Graham Rigby Lynn, M.B., I.M.S.; John Smith McCombe, M.B., R.A.M.C.; William Kenneth Morrison, M.B., R.A.M.C.; Douglas Chetham Pim, M.B., R.A.M.C.

Bar to Military Cross.

Captain Charles Albert Wood, M.C., M.B., I.M.S.

Military Cross.

Captains: Lionel Danvers Bailey, R.A.M.C.; Walter Bisset, M.B., R.A.M.C.; Hari Chand, I.M.S.; James Melvin, M.B., R.A.M.C.; Stephen Harold Middleton-West, M.B., I.M.S.; Carl Henry Rainhold, F.R.C.S., I.M.S.; Narendra Singhi Sodhi, I.M.S.; Charles Henry Neil Baker, I.M.S.; Edward Percival Allman Smith, M.B., R.A.M.C.

Temporary Captains: Alfred John Ireland, M.B., R.A.M.C.; Donald McDonald Wilson, M.B., R.A.M.C.; Arthur Budd, M.B., R.A.M.C.

ORDER OF THE INDIAN EMPIRE.

The following officers of the Indian Medical Service are appointed Companions of the Order of the Indian Empire in recognition of meritorious services in connexion with the war:

Lieut.-Colonel Felix Oswald Newton Mell; Lieut.-Colonel Bhola Nauth; Major David Munro.

FOREIGN DECORATIONS.

The following medical officers are included in the list of naval officers upon whom the King of the Belgians has conferred decorations for distinguished services rendered during the war:

Order of Leopold.

Commander: Surgeon-General Sir Arthur W. May, K.C.B., F.R.C.S., K.H.P.

Order of the Crown.

Commander: Deputy Surgeon-General Daniel J. P. McNabb.
Officer: Fleet Surgeon Kenneth H. Jones, M.B.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

LIEUT.-COLONEL F. D. BLANDY, R.A.M.C.(T.F.).

Lieut.-Colonel Francis Dawson Blandy, R.A.M.C.(T.F.), was reported as killed in action, in the casualty list published on August 27th. He was educated at the Middlesex Hospital, where he gained the Entrance exhibition in 1895, the Second Year exhibition in 1897, and the Senior Broderip Scholarship in 1900; and took the M.R.C.S. and L.R.C.P.Lond. in 1900, the M.B.Lond. in 1901, and the M.D. in 1905, and also the D.P.H. of Victoria University, Manchester, in 1905. After acting as house-surgeon and house-physician of the Middlesex Hospital, he went into practice at Tynemouth, Northumberland, where he was honorary surgeon to St. Oswald's Home, Cullercoats; to St. Aidan's Home, Tynemouth; medical officer in charge of the troops of Tynemouth Garrison, and Admiralty surgeon and agent. He joined the 1st Wessex (Exeter) Field Ambulance on May 3rd, 1910, became captain on January 6th, 1915, and had since been promoted to major and to lieut.-colonel.

MAJOR E. F. B. WILSON, S.A.M.C.

Major Edmund FitzGerald Bannatyne Wilson, South African Medical Corps, was killed in action on August 17th, aged 57. He was the fourth son of the late Rev. David Wilson, D.D., of Limerick, and was educated at Trinity College, Dublin, where he graduated M.B. and B.Ch. in 1881 and M.D. in 1890. Before the war he was in practice at Harrismith, Orange River Colony, where he was district surgeon and medical officer to the Central South African Railway.

CAPTAIN J. B. RAWLINS, R.A.M.C.(T.F.).

Captain John Branley Rawlins, R.A.M.C.(T.F.), was killed in action on August 16th. He was the elder son of the late Mr. John Rawlins of Erdington, Birmingham, and was educated at St. Mary's Hospital. He took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1914. He joined the 3rd London General Hospital as lieutenant on October 30th, 1914, and was promoted to captain after a year's service.

CAPTAIN C. WELLER, R.A.M.C.

Captain Charles Weller, R.A.M.C., was killed in the trenches on August 16th. He was the only son of Mr. Charles Weller of Redhill, and was educated at Guy's Hospital. He obtained the diplomas of M.R.C.S. and

L.R.C.P.Lond. in 1910. He took a temporary commission as lieutenant in the R.A.M.C. on November 1st, 1914, and was promoted to captain after a year's service.

LIEUTENANT C. M. ATKINSON, R.A.M.C.

Lieutenant Charles Mason Atkinson, R.A.M.C., was reported killed in action in the casualty list published on August 22nd. He was educated at University College, London, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1896. He went into practice at Ashford, Kent, where he was medical officer of the East Ashford Union Workhouse and infectious diseases hospital. He had only recently taken a temporary commission in the R.A.M.C.

Died of Wounds.

Captain J. C. Harris, R.A.M.C.

Died on Service.

CAPTAIN D. ARTHUR, M.C., I.M.S.

Captain David Arthur, M.C., I.M.S., died as a prisoner of war at Entelli, in Asia Minor, on July 31st, aged 32. He was the youngest son of the late Provost Arthur, of Airdrie, and was born on May 21st, 1885, and educated at Airdrie Academy and at Glasgow University, where he graduated B.Sc. in 1905, and as M.B. and Ch.B. in 1907. After acting as house-physician of the Western Infirmary, Glasgow, and as assistant medical officer of health of Cheadle, he entered the I.M.S. as lieutenant on July 31st, 1909, and was promoted to captain on July 31st, 1912. Before the war he was acting as medical officer of the 8th Rajputs, but was at home on leave in the summer of 1914, and returned to India at the beginning of the war. He went to Mesopotamia with the first force sent there, and took part in the landing at Mohammara, the fighting on the Karun river, the battle of Kurna, the capture of Kut-el-Amara, the battle of Ctesiphon, where he was wounded, and the siege and surrender of Kut. He was twice mentioned in dispatches, and was gazetted as a recipient of the Military Cross on October 19th, 1916. He is the officer called by the name of Gaspard in Major Barber's book, *Besieged in Kut and After*, a notice of which appeared in our issue of August 4th.

SURGEON-CAPTAIN R. A. BOSTOCK.

Surgeon-Captain Robert Ashton Bostock, Reserve of Officers, Scots Guards, died in London on August 17th. He was the son of the late Surgeon-General John Ashton Bostock, C.B., Scots Guards, was educated at Wellington and at St. Bartholomew's Hospital, and took the diplomas of M.R.C.S. and L.S.A. in 1885, and of L.R.C.P.Lond. in 1887. He entered the Army Medical Department as surgeon in 1886, and joined the 2nd Scots Guards as medical officer in 1887, but retired in 1898, and settled at Cefn Môr, Penmaen, Glamorgan. As an officer of the Reserve, he rejoined the colours on August 11th, 1914, and had been employed on recruiting duties at Whitehall.

Drowned.

Colonel T. Daly, C.M.G., R.A.M.C.

Wounded.

Major J. P. Kenny, Australian A.M.C.

Captain H. M. Anderson, R.A.M.C. (temporary).

Captain C. Dundee, R.A.M.C. (temporary).

Captain E. Edie, New Zealand Medical Corps.

Captain A. P. Gray, R.A.M.C. (temporary).

Captain F. Harris, M.C., R.A.M.C.(T.F.).

Captain R. I. Harris, M.C., M.B., R.A.M.C. (temporary).

Captain G. A. Hodgson, R.A.M.C.(S.R.).

Captain J. Kearney, R.A.M.C.(S.R.).

Captain W. J. Knight, M.C., M.D., R.A.M.C. (temporary).

Captain J. C. Metcalfe, M.C., R.A.M.C.(T.F.).

Captain I. Ogilvie, R.A.M.C. (temporary).

Captain J. E. Rutherford, R.A.M.C. (temporary).

Captain D. M. Smith, R.A.M.C. (temporary).

Captain H. S. Turner, M.C., R.A.M.C. (temporary).

Lieutenant Charles Dundee, M.B., R.A.M.C. (temporary).

Lieutenant C. J. E. Edmonds, R.A.M.C. (temporary).

Lieutenant and Quartermaster R. G. Johnston, R.A.M.C.

Lieutenant J. H. Mayston, R.A.M.C. (temporary).

Lieutenant T. D. C. Watt, R.A.M.C. (temporary).

Sister M. Benallack, Q.A.I.M.N.S., Reserve.

Sister S. Flanagan, Q.A.I.M.N.S., Reserve.

Missing.

Captain E. Newton, R.A.M.C. (temporary).
Captain A. K. Sinha, I.M.S.

DEATHS AMONG SONS OF MEDICAL MEN.

Alston, Ernest Alfred Brooke, Lieutenant-Colonel Northampton Regiment, fourth son of the late Surgeon-Major W. E. Alston of Sandgate, Kent, killed August 11th. He was born in 1877, educated at Tonbridge School, entered the Militia in 1895, and from there was gazetted to the Northampton Regiment, with which he served through the South African war, receiving the Queen's Medal with three clasps. He attained the rank of captain on July 26th, 1908, and on October 29th, 1914, was appointed second in command of the 5th Service Battalion (the first-service battalion raised) of his regiment, with the temporary rank of major. With it he went to France in May, 1915. A year later he was given the command of a battalion of the Duke of Cornwall's Light Infantry. He had twice been mentioned in dispatches.

Cahill, John Archibald, M.C., Captain Royal Berkshire Regiment, only son of Dr. John Cahill, of 12, Seville Street, Lowndes Square, S.W., killed August 16th, aged 27. He was educated at Epsom, and qualified as a solicitor in 1912. He joined the Artists' Rifles in 1907, volunteered at the beginning of the war in 1914, and went to the front, got a commission in February, 1915, and was severely wounded in the following month, and again on July 1st, 1916. He got his Military Cross last March.

Darling, Ronald Harry, Cadet, Royal Irish Rifles, youngest son of Dr. J. S. Darling of Lurgan, late president and treasurer of the Ulster Branch of the British Medical Association, was killed in action in the recent fighting in France, aged 18. Great sympathy will be felt by members of the Association with Dr. Darling in his bereavement.

Hamilton, Henry Edward Redmond, Captain Canadian Railway Troops, elder son of Dr. H. T. Hamilton of Barnes, was killed in action on May 19th, aged 31. He was an able and experienced railway engineer, and a member of the Institute of Civil Engineering of Canada. His brother is Captain C. E. P. Hamilton, D.S.O., R.A.M.C.

Irving, David Piercy, Second Lieutenant Royal Scots Fusiliers, third son of Dr. M. H. C. Irving, British Guiana Medical Service, aged 19. He was educated at Epsom College, where he was captain of the cricket eleven in 1915, and at the Military College, Sandhurst. He was gazetted to the Royal Scots Fusiliers in January, 1916, was reported wounded and missing on July 30th, 1916, and is now presumed to have been killed on that date.

Moore, Gerald F. H., Second Lieutenant Border Regiment, only surviving son of the late Colonel J. H. Moore, R.A.M.C., accidentally killed, August 12th, aged 31. Before the war he was in the Gold Coast Civil Service, and came home to join the army.

Moore, William, Second Lieutenant Royal Irish Fusiliers, elder son of Dr. A. P. B. Moore, Ashley House, Albertbridge Road, Belfast, was killed in action on August 16th, aged 24 years. He was educated at Campbell College and Queen's University, where he graduated with honours in 1914. After taking part in the suppression of the Sinn Féin rebellion, and acting as bombing instructor at Newtownards, he went to France in June last.

Penny, Bernard Willoughby, Second Lieutenant Royal Fusiliers, youngest son of Dr. E. J. Penny, of Yiewsley, Wolverton, Bucks, died of wounds August 18th, aged 22.

Reid, Donald, Lieutenant Highland Light Infantry, killed in action on August 17th, aged 19. He was the only son of Dr. J. Reid of Preston. He was educated at Preston Grammar School and Watson's College, and entered Edinburgh University with a view to joining the medical profession. He became a member of the University O.T.C., and passed out of it to the Cadet School at Gales, where he completed his military training.

Reid, John Shute, Second Lieutenant 2nd South Wales Borderers, attached to 87th T.M.B., only son of Dr. Edgar Reid (Major R.A.M.C.T.), of Swansea, died on August 17th from wounds received the previous day while leading his gun team into action, aged 20. He was educated at Wells House, Malvern Wells, and at Sedbergh School.

Shine, James Owen, Captain Royal Dublin Fusiliers, eldest and only surviving son of Colonel J. Shine, A.M.S., killed August 16th. He attained the rank of captain on April 28th, 1915.

Stockwell, Thomas Hodges, Lieutenant Canadian Forces, youngest son of the late Frederick Stockwell, M.D., of Bruton, Somerset, killed August 15th, aged 33.

Worthington, Winton, Private, Royal West Kent Regiment, only son of Dr. Humphrey Worthington, of Luton, Bedfordshire, killed August 3rd, aged 19.

MEDICAL STUDENT.

Johnstone, J. D., Second Lieutenant King's Own Royal Lancaster Regiment, killed July 31st, aged 29. He was the son of Conncillor T. Johnstone of Barrow, and was educated at St. Paul's School and at St. Bartholomew's Hospital, and had passed the first M.B. Lond. He enlisted early in the war, got his commission in 1915, went to France three months later, and had twice been wounded.

[If we shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

Ireland.

IRISH NURSING BOARD.

With the approval of the Royal College of Surgeons in Ireland, an Irish Nursing Board has been established for the purpose of standardizing the education of nurses, framing a curriculum, supervising examinations, and keeping a register of qualified nurses. The board consists of the president of the Royal College of Surgeons, with three members of the medical profession, and twenty-two nurse members elected by their fellow-nurses. It is hoped that the Irish Nursing Board will take the place in Ireland that the College of Nursing in London aims at taking in England. The co-operation of all Irish hospitals and institutions interested in the welfare of nurses and of the sick public whom they serve is desired by the board.

WAR AND INSANITY.

Dr. William Graham, Medical Superintendent of the Belfast District Lunatic Asylum, in his annual report says: "We are developing a wrong type of civilization, and this fact bears vitally on insanity and on war. The economic and social conditions of the world are ultimately the product of the spiritual ideals on which civilized life rests. Therefore, if the war should lead men to abandon the materialistic ends, or subjugate them to higher purposes, and so develop a new type of civilization, implying greater happiness and more mental equilibrium, might we not expect less insanity in the future? What we need is a startling indictment of a modern civilization with a demand for a new basis. That is a new spiritual ideal. I am certain that much of the insanity that prevails is the product of a false civilization. Civilization may be said to consist in the humanizing of man. We must learn to control our anger, to suppress antisocial and egotistic cravings, and to push into the unconscious impulses inherited from our animal ancestry. These impulses are frequently not changed or sublimated, but simply repressed. Down in the depths of the unconscious are the very same desires that actuated neolithic man—revenge, murder, and pitiless hate, and all uncharitableness. We find here, as it were, a recapitulation of the history of the race; as the different strata of the earth reveal the different levels of the evolutionary process, so in the unconscious may be detected different levels of cultured advance. War is a reversion to the original barbarism. It is an anachronism in the civilized world, a regression to the primitive instincts of the race. Hence, atrocities occur in proportion as the combatants surrender to these instincts. The responsibility for a war must rest ultimately upon the nation which first surrendered to its barbaric instincts, and thus dragged other people into the bloody maelstrom. To rouse the dormant powers of mischief that lie in the unconscious of the race, to stimulate them into activity by every device of ingenious wickedness—that is the crowning crime against civilization, and the nation guilty of it stands condemned at the bar, not alone of morality, but of rational thought. From the psychological point of view, militarism and ultra-pacifism must alike be rejected as unsound. The courageous and adventurous spirit, the aggressive and masculine impulses must be directed into new channels. Instead of wrecking the creations of civilization, these forces must be so controlled and used that they will work out man's greater good. War against disease, against the blind energies of nature, against human ignorance and misery, call for a courage and self-devotion so abundantly displayed amid the horrors of the European inferno. It is thus that the repressed instincts of a martial order can be 'sublimated' and the deepest cause of the war be destroyed at its root."

Canada.

THE MEDICAL SERVICES IN CANADA.

No satisfactory arrangement has yet been made as far as the control and care of invalid soldiers in Canada is concerned, and difficulties arising out of dual control by the military authorities and the Hospitals Commission have by no means disappeared. A memorandum was recently submitted to the Parliamentary Committee appointed to

inquire into questions relating to returned soldiers some months ago, by Surgeon-General J. T. Fotheringham, in which the serious drawbacks of the present situation were pointed out. The matter was also taken up at a special meeting of the Toronto Academy of Medicine on July 10th, when the following resolution was passed:

Whereas it has always been the custom to have wounded and invalided soldiers retained under military regulations until discharged, and treated professionally by physicians and surgeons responsible only to the military authorities; and whereas in Canada a plan has been followed whereby wounded and invalided soldiers are placed under the professional care of physicians and surgeons, who are made responsible to a civilian commission; and whereas the hospitals for the care of returned wounded and invalided soldiers, instead of being under the control of the Militia Department, have been placed under the control of the Military Hospitals Commission; and whereas up to the present the Commission have not assumed full control of these hospitals inasmuch as the medical care of patients is still, to a large extent, under medical officers responsible in part to the military authorities and in part to the Military Hospitals Commission, there exists a state of dual control which is eminently unsatisfactory, and does not ensure provision of the best treatment available for the soldiers;

Therefore be it resolved, and it is hereby resolved, that in the opinion of the Academy of Medicine, Toronto, there should be one united medical service in Canada, and that the medical care of all soldiers, invalided or otherwise, should be placed directly under a surgeon-general, to be known as Surgeon-General of Canada, with direct responsibility to the Honourable the Minister of Militia, and with a seat on the Militia Council; further, that the Surgeon-General of Canada should absorb the duties of Director of Medical Services, Invalids, and be chief medical officer of the Military Hospitals Commission, and be *ex officio* a member of the Military Hospitals Commission and of its executive. Further, that Surgeon-General Fotheringham, who has been recalled from overseas to become Director of Medical Services, Invalids, should be appointed forthwith as Acting Surgeon-General of Canada; further, that the views expressed by Surgeon-General Fotheringham in his evidence before the Parliamentary Committee on Returned Soldiers at its sitting on June 12th, 1917, are generally endorsed.

THE TORONTO ACADEMY OF MEDICINE.

The Toronto Academy of Medicine was formed in March, 1907, with 184 resident and 3 non-resident fellows; it now has 485 fellows—434 resident, 42 non resident, 4 life, 4 honorary, and one corresponding. The progress of the library of the academy has been most satisfactory, and at the tenth annual meeting, on May 1st, the president, Dr. John Ferguson, suggested that practitioners in Ontario should be asked to send any rare book or manuscript or any information relating to the history of medicine in the province to the academy, and that a fund should be opened for the purchase of old and rare editions and works on the history of medicine. He suggested also that the transactions of the academy should be published, a course which, he believed, would serve as a stimulus in maintaining a high standard in contributions made to the academy and in advancing the cause of medical education in Toronto. Dr. D. J. Gibb Wishart was elected president for the session 1917-18.

WORKMEN'S COMPENSATION ACT IN ONTARIO.

The Workmen's Compensation Act was recently amended by the Ontario Legislature. As the Act stood previously, no provision was made for the payment of the doctor's fees in cases of accident or illness resulting from accident. An arrangement has now been made by which the Compensation Board will defray all the medical, surgical, hospital, and nursing expenses incurred by an injured employee for thirty days after the accident. The amount will be paid out of the Board's Accident Fund, and employers are not permitted to collect money from employees for this purpose unless a first-aid organization which is acceptable to the Board has been provided.

Australia.

STATE CHILDREN RELIEF BOARD, NEW SOUTH WALES. In New South Wales the State maintains no barrack "homes" for the waif, the stray, and the orphan, but boards them out in the homes of other families, or of their own if there be a widowed mother or other relative remaining. The plan has just been through the fire of a

severe criticism. The Report of the State Children Relief Board for 1915-16, by its president, Mr. Alfred William Green, states that the press had given prominence to reports of cases of alleged ill treatment or neglect of State children. The majority of these were found upon inquiry to be quite baseless. In some instances the children were not wards of the board, but had been placed out by private establishments or by their own relatives, and neglect or ill treatment had been detected by the Board's officers in the course of usual inquiry.

The experience of the department is that neglect or ill treatment, when it does occur, takes place in the case of children placed with their own relatives. . . . There are, of course, instances in which the boarding-out system is abused, but these are rare indeed. . . . Every system has its defects, and the boarding-out system is no exception. The contention is, however, that boarding-out, as a system for the upbringing of neglected and dependent children, has fewer defects than any other system established for a similar purpose. Wherever it has been tried under reasonable conditions it has proved successful. Its outstanding merit is that any abuse of it is readily detectable—it is practised in the light of day; the community as a whole is competent to inspect and criticize it from individual instances; it is not possible for neglect to occur at any time to any large number of children, nor can neglect or ill treatment occur in any individual instance for any length of time without the whole community conniving at it—the school teacher, the clergy, the police, the neighbours all unite in natural co-operation with a natural system. . . . The experience of this State in securing the happiest results from boarding-out corresponds to that elsewhere. . . . Suggestions made that this system should be replaced by a system of State boarding schools must, therefore, be regarded as due to general ignorance of the whole question as well as total disregard to the results achieved in New South Wales.

The proportion of State children is 6.6 per 1,000 of the total population of the State. Rather more than half are with their own mothers. The actual cost to the State for each child boarded-out apart from its parents was £17 Os. 11d. Allowances to widows and deserted wives works out at an actual cost of £10 10s. 8d. for each child, the costs of other Australian States which retain the boarding school system are set out, and also some of the charges paid in London. There can be no doubt of the economy of the boarding-out system.

Special arrangements are made for difficult cases. Truant and uncontrollable children are housed with families living at Hawkesbury River, and a Government launch calls for them daily and takes them to and from school. It is stated that the plan works well. There are special cottage homes for weak and ailing children, and for the feeble-minded. Arrangements are made to apprentice the boys and girls, mostly in the country districts. The boys go to farms and the girls to domestic service. It is proposed to establish special trades schools for the children.

Besides this the Board is responsible for the working of the Neglected Children and Juvenile Offenders Act. It controls farm homes and industrial schools for young offenders, and takes oversight of those discharged on probation. It has the supervision of the children licensed for street trading. The Children Protection Act, which requires the registration of children under the age of 3 years who are taken into "nursing homes," is administered by the Board, also the licensing of theatres for child performers. Finally, its officers play the part of school attendance officers to the State schools. Altogether the work done by this Board appears to be admirable.

As the result of the law making the muzzling of dogs compulsory in Cuba, there has been a notable reduction in the number of cases of hydrophobia. Whereas in 1914 there were fourteen deaths, in 1915 and 1916 there was one each.

THE United States Secretary of State for War has approved an order creating a sanitary corps under the Medical Department in the army. It will include various classes of experts in sanitation, sanitary engineering, and bacteriology, and men skilled in the work of supply, transport, and storage in connexion with the Medical Department. The total number of officers in the corps is not to exceed 1 for every 1,000 of the total strength of the military forces authorized from time to time in accordance with law. There will be no rank above that of major, and no officer of the medical corps will be appointed to the sanitary corps.

Correspondence.

REAMPUTATIONS.

SIR,—Captain Sampson Handley, in the *JOURNAL* of August 25th, has forestalled me in a contribution upon the subject of reamputations which I had proposed sending you. But a few additional remarks may serve to support his opinions, as well as to indicate what appear to me some advantages in the method I practise.

He acknowledges the difficulty of obtaining efficient Gigli saws. I have always used the chain saw; and the method of its employment is as follows: An incision of required extent—two to three or four inches—is, in the case of the thigh, carried up the outer side of the limb, and hard down to the portion of the bone it is designed to remove. This incision may or may not divide vessels that may need to be ligatured. By means of an aneurysm needle curved laterally a silk suture is carried round the femur at the level at which the bone is to be sawn through. This can be fairly easily effected by forcibly retracting the walls of the incision. The silk suture is disconnected from the eye of the needle, and used as a guide and tractor for introducing the chain saw. The operator stands at a convenient height above the stump, the latter being firmly held down by the assistant. To prevent the saw locking in the compact bony tissue, and to facilitate its up and down action, carbolic oil is constantly dropped upon one side of the chain; this, trickling down to the seat of severance, very effectually lubricates the parts. In only then remains to detach the freed fragment of projecting bone. The advantages of this method of reamputation—in principle that adopted by Captain Handley—have been sufficiently well indicated by him; and although the technique in performance of the two methods differ, the results in both instances appear equally good. As nearly all the cases are more or less septic, it is of no little moment that the area of fresh tissue exposed should be as small as possible, so that the risk connected with infective absorption may be reduced to a minimum. And equally important is it to remove only as much bone as can be efficiently covered by the practically undisturbed soft tissues; in other words, the stump should be rendered as long as possible. In both these important particulars, not to mention others of a minor degree, these methods of removal of projecting bone, either by the Gigli or the chain saw, fulfil the objects aimed at, and should commend themselves for adoption in all suitable cases, thus taking the place of the commoner practice of reamputation by newly formed flaps.

A detail in the dressing of more particularly painful stumps which I have carried out in several cases is, I think, of some practical value and worthy of more extended application. Some stumps seem very sensitive to movement or manipulation of any kind; and the process of removing or applying a bandage is not infrequently fraught with a great deal of discomfort and even distress to the patient. To mitigate these drawbacks in the usual method of dressing I have had wire cages constructed which can be lightly lined or packed with antiseptic dressings and into which the stump can be slipped and rest upon a bed of soft tissue. Thus, little or no pressure is exercised upon the wound; and perfect freedom is given to the outflow of the discharges. These "stump cages" have been made for me by Messrs. Alexander Cousland and Sons, wire workers, 3, Mitchell Street, Glasgow, at the moderate price of 3s. 6d. each.—I am, etc.,

Glasgow, Aug. 27th.

A. ERNEST MAYLARD.

A SIMPLE METHOD OF BLOOD TRANSFUSION.

SIR,—I read in the *BRITISH MEDICAL JOURNAL* of April 21st a paper from James Buchanan, M.B., on a cannula for direct blood transfusion. This apparatus is made of glass and curved in the shape of an 'S'.

I would like to remind you of a paper I published in the *Correspondenzblatt für Schweizerärzte* (No. 77, 1916) after having been head surgeon in a Red Cross hospital at Lyons (France).

You will find (p. 17) a drawing of the cannula I used for blood transfusion; this cannula has been made purposely

for me on my indications. I have used it ever since with complete success whenever blood transfusion had to be undertaken in the service of my beloved and lamented "Chef" Professor Kocher in Berne.

You may see that Dr. J. Buchanan's cannula is identical with mine. After the publication of my paper in 1916 I heard that the American surgeon, Fauntleroy,¹ had also made use of a cannula of the same kind. Dr. Buchanan will have to acknowledge, as I had to do then, that there is nothing new under the sun, and that it is very difficult nowadays to be first in a new invention.

The technical method of your author is identical to that of Tuffier² in Paris and Bérard³ in Lyons. I have somewhat altered this method, as you will see in a new publication which I sent last spring to the University of Berne, and which will appear shortly in the *Swiss Correspondenzblatt*.—I am, etc.,

C. A. PETTAVEL, M.D.,
Ancien Chef de Clinique du Professeur
Th. Kocher à Berne.

Neuchâtel (Suisse), Aug. 12th.

IMMUNITY AND TUBERCULOSIS.

SIR,—I am unable to accept the explanation of the extinction of the Tasmanians which Dr. Glover gives in the *BRITISH MEDICAL JOURNAL*, May 12th, p. 633, because it deals only with the lesser side of immunity—the acquired.

It has been argued, to the point of conviction, that acquirements are not transmitted, and if this conclusion of biologists be correct, it follows that "the presence or absence of previous racial infection—that is, the presence or absence of immunization"—does not, as Dr. Glover states, explain the extinction of the natives of Tasmania by tuberculosis.

Natural immunity is an innate quality of the species that protects humanity against such a disease as tuberculosis. Acquired immunity protects the individual against such a disease as small-pox. Natural immunity becomes more intense as disease eliminates those who have had transmitted to them a low degree of this quality, and as those who have a high degree transmitted to them become more numerous. Thus it comes about that the Jews, who have been in constant contact with tuberculous infection, show a high degree of racial immunity.

It is admitted that the action of tuberculin is due to the toxin of the organism of tuberculosis. Therefore, if it be possible to acquire immunity against tuberculosis, the injection of this active principle of the disease should set up acquired immunity in the as yet uninfected individual. The belief that glandular bovine tuberculosis in children protects them against extensive human tuberculosis in adult life seems to arise from mistaking natural for acquired immunity.

The cases that recover under sanatorium treatment are those that possess a considerable degree of natural immunity, the balance of which has been upset by devitalizing processes in the presence of infection. The war brings this out most clearly.

Natural immunity indicates that:

1. The State should make great efforts to destroy infection and discourage marriage amongst those who are tuberculous.
2. That sanatoriums should be for those who show early tuberculosis under the stress of vicious environment.
3. That hospitals should be provided for infectious cases.
4. That notification should not be abused so as to make consumptive colonies in the so-called good-for-consumption places.—I am, etc.,

W. STAPLEY, M.D., M.R.C.V.S., D.V.Sc.
Cambridge, New Zealand, June 27th.

THE FUTURE OF VOLUNTARY HOSPITALS.

SIR,—The correspondence with the Ministry of Pensions as to the hospital treatment of disabled soldiers makes the present a suitable opportunity for the profession to consider the whole hospital question.

The subject would have been brought before the Annual

¹ A Simplified Method for the Transfusion of Blood, *Medical Record*, September 3rd, 1910.

² Tuffier: La transfusion du sang, *Presse Médicale*, 1912, No. 62.

³ Bérard and Lumière, *ibid.*, 1915, No. 41.

Representative Meeting by a rider of the Nottingham Division if the Ministry of Health scheme had been discussed in detail. The rider in question was: "That all hospitals under the public scheme should be State controlled."

The position of hospitals in this country, especially in industrial districts, has undergone a radical change during the past twenty years. They are no longer, strictly speaking, charitable institutions. They are supported very largely by employers of labour and by organized collections among workpeople. As a consequence of the latter fact, the workpeople repudiate the idea of charity; they have their representatives on the hospital boards and they claim the institutional treatment as a right for which they are paying. To the employers of labour and the insurance companies the hospitals are a means of getting the workers back to their employment quickly, and their support is a mere matter of business.

The only people who regard the hospitals as charitable institutions are the medical profession and a minority of the subscribers who give their support from purely charitable motives.

In this Division we consider that the Council's scheme, whereby the voluntary hospitals continue as at present and are subsidized by the State for some of their patients, is unpractical if not unworkable.

I hope some discussion upon this subject will follow which may be helpful to the Council in their future deliberations.—I am, etc.,

C. J. PALMER,
Representative Nottingham Division.

Mansfield Woodhouse,
Aug. 20th.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

SIR,—I have seen the Circular (M.I.), dated August 4th, which is being sent by the Medical Secretary of the British Medical Association to secretaries of Local Medical and Panel Committees, with reference to the above subject, from which it would appear (par. 4), that the Commissioners submitted certain proposals on the above subject to the Insurance Acts Committee of the British Medical Association, to which the latter agreed, stipulating that the arrangements contemplated should be regarded as experimental, in which view the Commissioners concurred.

Apparently the proposals referred to were (par. 5):

1. That the disabled men discharged in future shall be attended under the same regulations as those at present applying to "temporary residents," and at the same rate of remuneration.

2. But that if the 9s. paid into the pool should not be sufficient to pay 100 per cent. of the amounts proved to be due for general practitioner treatment of disabled men, the Treasury will make up the deficit.

3. Concerning the men already discharged: It will be optional for practitioners to retain them on their capitation lists, or attend them in future on the attendance basis, as from the first day of the following quarter.

Does the executive of the British Medical Association, then, wish the practitioners throughout the country to regard this as the firstfruits of the collective bargaining which the British Medical Association has volunteered to carry on for the profession?

Let us mark the diplomatic steps in this important piece of collective bargaining.

1. The Commissioners submit certain proposals.

2. The Insurance Acts Committee of the British Medical Association accept them with the proviso that they be experimental and capable of revision.

3. The Commissioners concur in the proviso and proceed to draft the regulations.

And these proposals, which were so glibly settled, concerned perhaps the most vitally important matter which has been awaiting a settlement ever since the war began.

This is the matter which has been carefully held over so that neither side should be committed to a hasty decision, which has been kept in the background, and for a settlement of which practitioners have waited patiently and hopefully, while they found

(a) Their lists being deteriorated at least 50 per cent. by the removal from them of all the strong, healthy lives of men of military age, leaving them only old men, women, and growing boys, the part of their lists which always meant working at a loss.

(b) The substitution of a large number of women of very mixed standards of health, most of whom are engaged upon work the character of which is such as to make them frequent visitors to their panel doctors.

(c) The absence of any suggestion that a war bonus or other form of recognition was felt to be due to the practitioners who have been subjected to these disabilities, and who are at the same time helping the war by carrying on the work of absent practitioners at half fees.

(d) Their notification fees are reduced from 2s. 6d. to 1s. so that the paltry sum of £23,000 should be saved the country, while the same week they saw the railway men (organized labour) being granted a bonus which will cost the country £7,500,000 per annum.

Through all these experiences they waited, I say, because they felt certain that due and fair consideration would be given to all of them when the time came for the all-important matter of fair remuneration under the altered conditions to be considered.

This matter of a fair basis of remuneration is of such vital importance that everything else may be said, in a way, to be dependent on it. It must be adequate, it must be fixed, and it must be paid punctually.

The suggested settlement is:

1. For these unfortunate disabled men—who will in the future probably constitute the worst element in our lists—we are offered the same contract rate as for the strong and healthy and employed persons—9s. a head—which, of course, we know by experience, means 7s. But, as a great concession, if the pool is not sufficient to pay in full, the Treasury will make up the deficit.

2. The payment is to be on an attendance basis on the same principle as that of "temporary residents"—that is, the system which is universally conceded to be so troublesome and so bad, that numbers of doctors prefer to attend such temporary residents as they cannot avoid taking, for nothing, rather than compile the necessary literature about them.

3. With regard to the men already discharged, we can choose whether we treat them on the same basis as those to be discharged in future, or on the capitation basis at the 7s.

Is this, then, what we have waited for? And is this all the British Medical Association could do for us? Here was an opportunity to wipe off scores of grievances and to heal dozens of scars. It was a grand opportunity for the Government to offer a generous recognition of all that the medical profession has been doing, and is ready to do in the future.

The least that should have been offered was a capitation fee of 10s. a head for all disabled men over and above the cost of drugs and appliances. The medical profession would accept that—it is due to them, and it is due to the discharged men. The Treasury should find the money; it is a national charge to which no one will object, and the approved societies should be allowed to have all the contributions paid in respect of the men since they joined the colours as a set-off against the loss they will incur in sick pay.

I call on every practitioner in the country, whether on the panel or not, to say that he will accept those terms, and on no other terms will he accept any responsibility for attendance upon these poor fellows. It is a national job, and as such it must be carried out.

With regard to the British Medical Association, I think this ought to convince all who still remain unconvinced that the British Medical Association and politics must part. Either the executive of the British Medical Association are persons who can be exploited by the clever politicians at the Insurance Commission just as they like, or they think the practitioners throughout the country are persons who can be exploited by the British Medical Association Executive at the bidding of the Insurance Commissioners.

I would earnestly ask every practitioner in the country—insurance or other—to send me a post-card saying whether or not he agrees with me, and I will then indicate the next step to be taken. There must be no delay; the regulations are being drafted. It is no use to say that this matter will arise as part of a general settlement after the war. It is a matter which should be settled now. It is the first skirmish in the big fight that is bound to take place, and if we let the first skirmish go by default it will be a bad omen for the result of the whole war.

We must act now.—I am, etc.,

J. A. BELL,

Chairman Gloucester Local Medical and Panel Committees.

55, Barton Street, Gloucester, Aug. 16th.

MINISTRY OF HEALTH.

SIR,—The unwieldy scheme for the immediate establishment of a Ministry of Health has been generally approved at the Annual Representative Meeting. The Council has been urged to secure its acceptance by the Government "so far as possible." I am writing to ask those members of the British Medical Association who disapprove of this "rushing" policy to form an Internal Reform Committee to thwart the perpetration of such a political and social outrage on the members of the medical profession now serving abroad. A strong political clique, headed by an ambitious Minister, is, through a command of the press, indulging in an attempt to foist immature and ill-considered legislation of this nature on the public. It promulgates its scheme of selling the medical profession fighting overseas under the despicable guise of national expediency and infant welfare. It has captured members of the Association who are not serving overseas, and unless an indignant protest is made it will probably succeed in hoodwinking the nation and its legislature.

The establishment of a Ministry of Public Health will prove a sound measure. As one who has devoted years to the study of this question, and who has prepared a scheme which has been submitted to the Government, I can safely prophesy that a well-worked-out and thoroughly discussed scheme can be devised which would in later years be of enormous benefit to the administration of medical affairs in the State and to the national health. But this is a period of war. Such an innovation cannot with any sense of justice or reason be described as a war measure. It cannot be defended on any ground of national expediency or urgent necessity. Before such schemes are placed on the statute book, the medical profession as a whole, especially the younger men who will have to work the details of the administration, ought to have an opportunity of hearing the question discussed in all its bearings, and such schemes can wait till the period of reconstruction. It is not a little astonishing that, with the example of the Insurance Act and the chaotic state of its administrative problems before us, a deliberate and indefensible policy of forcing the establishment of a medical bureaucracy on the State without full and mature consideration and without expert advice should be attempted while the country is at war and while a third of the qualified medical men are scattered on active service overseas—in Mesopotamia, Malta, Salonica, Egypt, Italy, Africa, and France. Surely such men have rights as well as duties. They are doing their share. Performance of duty ought to necessitate careful guardianship and preservation of their rights by the State, their fortunate colleagues at home acting as sentinels to repel any encroachments. But the age of such principles has flowed past us in the tide of war. The Prussian type amongst us is in the ascendant. This is the period of the burial of political rights, of the destruction of professional *esprit de corps*, and of the deliverance into political slavery of absent colleagues engaged on a noble duty.

Little can be said again \ special legislation dealing with infantile mortality. This may or may not be necessary. No sound argument can be brought against a preliminary discussion of a scheme for establishing such a Ministry, but to acquiesce in a proposal for its immediate establishment under present conditions is not statesmanship. It is not even clean politics. It is political burglary. Such an outrage can scarcely be disguised under the cloak of supposedly representative medical opinion or of national well-being. Have we thrown overboard the principles of true representative government? Has any stay-at-home medical man the right—even if he has the conscience—to shackle his colleagues *in absentia* with legislation of far-reaching effect and with future responsibilities of professional and national importance? Theft of a medical practice is unprofessional conduct. Is embezzlement of political rights the acme of noble statesmanship and patriotism? The following remarks pass muster at the Annual Representative Meeting as the concentrated essence of our wit and political statesmanship (vide daily Press):

1. "Are we at home to be old women? The proposal to postpone effective consideration till after the war is the proposition of lawyers, the last refuge of the destitute."

2. "War time is the time when much desired changes should be made."

No wonder the political wire-pullers snap their fingers at our manoeuvres. One can scarcely hope that the age and sex change suggested will take place—at least physically.

The second is a political maxim which should be crushed at once. It is unsound, dishonest, and Prussian. War time is the time to win the war and to promote only such changes as have a direct effect in the securing of victory. The establishment of a Ministry of Health now will not shorten the war by a day. The professional Prussian at home should be fought as strenuously as his international prototype abroad. If those who disagree with the decision of the Representative Meeting will make an effort to fight this outrage, the common sense of the nation can be won to their side. But we must be up and doing; the press will probably be closed to us. Professional despots may thwart us, but there is always the direct appeal to Parliament, either by a petition, or, preferably, by a memorandum addressed to every member of each House.—I am, etc.,

H. B. MORGAN,
Temporary Captain R.A.M.C.

B.E.F., France, Aug. 2nd.

MEDICAL STUDENTS IN AND OUT OF THE
RANKS.

SIR,—There are a large number of medical students who, at the outbreak of war, 1914, inspired by patriotism, voluntarily left their studies to join the fighting forces. After the publication of A.C.I. No. 2290, dated December, 1916, many applied to be allowed to return to qualify, feeling it to be now their duty to the State, owing to the coming shortage of medical men. The War Office would not allow temporary demobilization (granted with the right to wear the uniform of their late regiment) until qualified and able to transfer to the R.A.M.C., but insisted on those holding commissions resigning same. The consequence is that those so situated, now always wearing plain clothes, are continually being subjected to insults in public, being classed with conscientious objectors and those stricken with syphilis.

Those who joined the senior service, however, as surgeon-probationers have, in many cases, been allowed to return to qualify. They have been courteously thanked for their past services, temporarily demobilized, and allowed to retain the use of their uniform. Another outstanding injustice to those who have served in the army is the fact that those who did not answer their country's call are now qualified or nearly so, and will be senior to their more patriotic fellows who volunteered at the commencement of hostilities and are not granted even a day's seniority for past services when they are able to obtain their commissions in the R.A.M.C. Like "J. A. A.," in his letter in your JOURNAL of July 21st, we are forced to ask, "Does patriotism really pay?"—We are, etc.,

August 27th.

EXCOMBATANTS.

SIR,—This is a subject of some importance, not only to the profession, but to the army, and I venture to urge that it should not be laid aside just now. The war may very likely end next year, and I ask through your columns what is the British Medical Association and what is the General Medical Council prepared to advise with reference to those students who so unselfishly answered the call of their country in 1914? I respectfully press this question now, and I should like to know from some one in authority what it is intended to do about them. Can Sir A. Keogh enlighten the minds of those of his medical brethren whose sons have so nobly given of their best? Surely the British Medical Association will make a move in so urgent a matter. It would be interesting to know to what degree the R.A.M.C. is now suffering or by next year will be suffering by reason of the supineness of those in authority in 1914. Some one has the figures. Let them be produced.—I am, etc.,

Manchester, Aug. 27th.

BASIL W. CONWAY.

THE ARMY MEDICAL CORPS AND ITS WORK.

SIR,—May I offer a few words of appreciation to the author, whoever he may be, of the article in your issue of August 18th entitled "The Army Medical Corps and its Work"?

After eighteen months' experience as a regimental

medical officer in France I confess that I commenced to read his article in a rather critical mood. I finished it with full appreciation of a well-expressed concise epitome of the conditions of medical work in the line, and am awaiting his next contribution.—I am, etc.,

B.E.F., France, Aug. 20th.

CAPTAIN R.A.M.C.

Obituary.

JOHN BELL FISHER, M.D., D.P.H.,

PRESIDENT OF THE BORDER COUNTIES BRANCH.

It is with deep regret that we record the death of Dr. Fisher of Whitehaven. For some twelve months he had been suffering from symptoms of angina pectoris. He had been very much overworked of late, and he left home on August 15th for a short holiday, travelling by sea to Liverpool. He was taken ill soon after his arrival and died on August 18th, aged 60 years.

A native of Whitehaven, he was esteemed and respected by all classes of the community among whom he lived and worked, and his loss will be keenly felt by a large circle of friends. He studied medicine at Edinburgh, graduating M.B., C.M. in 1880; he took his M.D. degree with commendation in 1902 and the D.P.H. Edin. in 1908. Settling in practice he was in 1883 elected honorary surgeon to the Whitehaven and West Cumberland Infirmary and held this office for twenty-two years when, owing to the claims of private practice and his other appointments, he relinquished the office. He was appointed medical officer of health for Whitehaven borough twenty-two years ago, and he was also medical officer for the Whitehaven Town and Harbour Boards, school medical officer to the Whitehaven Education Committee, medical officer for the Rural District of Whitehaven, and head of the recently established Whitehaven Maternity and Child Welfare Centre. He took a keen interest in his public health work, and the writer of this notice is indebted to the County Medical Officer of Health, Dr. Morison, for the following brief appreciation: "Few men, I think, did their work more thoroughly and with less parade than the late Dr. J. B. Fisher. His loss will be severely felt in the public health service of the county. He was most conscientious and thorough in the discharge of his duties as medical officer of health, and only those who were brought intimately into contact with him in his work, as I had the privilege of being, can realize the immense amount of work he did. His genial presence, as well as his able and willing help, will be sadly missed by his colleagues." Dr. Fisher was an active and loyal member of the British Medical Association, and had the thorough confidence of his professional brethren, as is shown by the fact that he was in 1912 elected chairman of the English Division of the Border Counties Branch. He was also chairman of the Provisional Medical Committee for Cumberland in 1912. For his services in this latter capacity his fellow practitioners presented him with a piece of plate. From 1914 until his death he was president of the Border Counties Branch, and his presidential address on National Health Insurance was published in the *JOURNAL* of July 25th, 1914. He was also chairman of the Cumberland Medical and Panel Committee, and was most assiduous in his attendance at its meetings. Quite recently Dr. and Mrs. Fisher celebrated their silver wedding. Dr. Fisher is survived by his wife, one son (a lieutenant in the army), and one daughter, with whom much sympathy is felt in their sudden bereavement.

The funeral took place at Whitehaven on August 22nd. There was a large attendance, including the Mayor and Corporation, the borough officials, members of the medical profession, and a representative gathering of old patients and professional and trading gentlemen of the town and neighbourhood, all testifying to the esteem and respect in which Dr. Fisher was held.

WILLIAM HENRY SYMONS, M.D., M.R.C.S., L.R.C.P.,
D.P.H., M.O.H. BATH.

THE death occurred on August 25th, at the age of 63, of Dr. William Henry Symons, Medical Officer of Health for the City of Bath. He was educated at Taunton, first adopted chemistry as his vocation, and became analytical chemist to Messrs. Idris, aerated water manufacturers.

He also practised as a consulting chemist and was appointed examiner under the Pharmacy Act. While assistant demonstrator in *materia medica* at St. Bartholomew's Hospital he decided to qualify in medicine with a view to specializing in sanitation. He became a student at St. Bartholomew's, and in 1894 he took the diplomas of M.R.C.S. and L.R.C.P. Lond. and the M.D. degree of Brussels, while in the following year he obtained the Diploma of Public Health both at Oxford and Durham. Dr. Symons was also a Fellow of the Institute of Chemistry, of the Microscopical Society, and of the Royal Sanitary Institute. After serving as medical officer of health in the parish of St. George-the-Martyr, London, he was elected, in 1896, M.O.H. of Bath, and during his tenure of office he remodelled the health department of the city and modernized the meteorological department. Dr. Symons was a pioneer in the campaign against flies and made a number of breeding experiments with house-flies.

WITH the death, on March 11th, of Dr. SELWYN HARVEY, of South Kensington, there disappeared a courtly physician of the old school. He was a contemporary of the late Dr. Pyc-Smith at Guy's Hospital, to which he was greatly attached. Dr. Harvey bore his advanced years exceptionally well to the last, continuing in active work until quite recently. He had practised for many years in Boulogne before settling in London in 1890. Of equable temperament and unchanging kindness, he was always happy to assist younger practitioners, whether by advice made valuable by his own ripe experience, or, whenever possible, by generous handing on of work. A man of cultivated taste and of varied interests, as well as of attractive and sterling character, Dr. Harvey will be greatly missed by a large circle, and by none more than by the writer—himself an old "Guy's" man.

MR. THOMAS SANSOME died on August 13th at his residence at West Bromwich, aged 75. He was born at Evesham; he received his medical education at Sydenham College, Birmingham, and took the diploma of M.R.C.S. Eng. in 1866, and that of L.S.A. in 1868. He went to Bromwich about fifty-three years ago as an assistant to the late Dr. Male, and succeeded to the practice on the death of his principal shortly after. From 1871 to 1908 he held the office of honorary surgeon to the West Bromwich District Hospital. On relinquishing the post, in which he was succeeded by his son, who is now mayor elect of the borough, he was appointed consulting surgeon. He was a member of the West Bromwich Division of the British Medical Association, and of the Midland Medical Society. In 1902 he was appointed to the commission of the peace; before the ordinary business of the local police-court on August 16th the chairman referred to the loss the borough had sustained in the death of Mr. Sansome, and expressed his sympathy with the family in their bereavement.

DR. GAETANO RUMMO of Naples, who died suddenly a short time ago at the age of 64, was one of the most prominent figures in the medical profession of Italy. He studied at Naples, and after graduation worked in Paris under Charcot, Sée, and Potain, and in the laboratory under Vulpian and Cornil. While still quite young he won by competition the appointment to the chair of medical pathology in the University of Siena; he was successively professor of the same subject at Pisa, Naples, and Palermo. After a time he returned to Naples, where he soon gained a leading position as a clinical teacher. He was the author of a long series of publications on cardiokynesis, leukaemia, pleurisy, the toxicity of blood serum, the pathology of the nervous system, cardiophtosis (a disease which is sometimes called after him), and many other subjects. Outside his native country Rummo was best known as the founder and editor of the *Riforma Medica*, one of the leading medical journals of Italy. For twenty years it was a daily periodical—the only one in the world devoted to medicine; it still continues to flourish as a weekly. Rummo was a member of the Chamber of Deputies.

The Services.

EXCHANGE.

QUARTERMASTER, home service field ambulance, R.A.M.C., stationed Ireland, desires exchange quartermaster in field ambulance on active service in France. Address, No. 2900, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

Universities and Colleges.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subjects indicated:

SURGERY.—*J. L. D. Buxton, *C. A. W. Chapman, *D. C. Clark, *W. Fletcher Barrett, *A. Selby Green, *D. E. Hearn, *S. G. Mahomed, *E. J. G. Sargent, *C. Segal.
MEDICINE.—*G. S. Ashby, *W. F. Barrett, *J. Behesnilian, *C. G. Bunn, *C. A. W. Chapman, *D. C. Clark, *E. F. Deacon, *E. W. Diggett, *F. C. M. Gabites, *D. E. Hearn, *I. Liberman, *A. G. Curzon Miller, *E. J. G. Sargent, *G. R. Sharp, *L. Zarchi.
FORENSIC MEDICINE.—W. F. Barrett, D. C. Clark, A. S. Green, D. E. Hearn, B. A. M. Henderson, I. Liberman, G. L. Mitchell, E. J. G. Sargent.
MIDWIFERY.—W. F. Barrett, D. A. Dyer, B. A. M. Henderson, I. Liberman, J. Stephen.

* Section I.

† Section II.

The diploma of the society was granted to W. Fletcher Barrett, C. A. W. Chapman, D. C. Clark, E. W. Diggett, A. Selby Green, D. E. Hearn, E. J. G. Sargent, C. Segal, and G. R. Sharp.

Medical News.

AT Hinckley, on August 23rd, Dr. A. W. Jenkins was presented with an address and a pair of bronzes in recognition of his ten years' valuable work as honorary surgeon to the Hinckley and District Cripples' Guild.

COLONEL C. GORDON WATSON, C.M.G., F.R.C.S., A.M.S., assistant surgeon to St. Bartholomew's Hospital, London, and Dr. William E. Audland of Wellingborough, have been appointed Knights of Grace of the Order of St. John of Jerusalem.

THE Rockefeller Institute for Medical Research has, it is stated, undertaken to supply the allied armies with an antitoxin serum believed to be effective against gas gangrene. Cultures of the bacillus were obtained in Europe last year by Dr. Carroll G. Bull and Miss Ida W. Pritchard, and these investigators have experimented on animals with results said to be satisfactory.

MR. E. TEMPLE THURSTON gave in the *Sunday Pictorial* for August 26th some account of the suggestion of the French Government to raise a lasting monument to those who have fallen in the war, by forming a road from the Flemish coast to Alsace, planted on either side with forest trees. The scheme would include the preservation in their present state of the devastated villages and the careful tending of graves.

AN interesting addition has recently been made to the Erskine Hospital for Limbless Men. Lieutenant Napier, the military governor, has presented to the institution Erskine Ferry Inn, an old building beautifully situated on the banks of the Clyde just outside the hospital. Therein are provided convenient refreshment and rest rooms for visitors calling on patients. The opening ceremony was performed by Lady Dunlop, wife of the Lord Provost of Glasgow, and Sir William Macewen, who was in the chair, said that although the hospital was large every part of it was needed, and already about 250 beds had been added to it at the urgent request of the War Office.

AN article in a recent issue of *Le Journal*, Paris, states that the number of permanent nurses employed in the French military hospitals at the outbreak of war was eighty; the number of nurses now temporarily employed is 3,000. In addition there are 62,000 nurses belonging to the various French Red Cross Associations, of whom some 6,000 are in the army zones. The writer of the article makes an eloquent reference to the manner in which the nurses of friendly nationalities, to the number of about 10,000, have come forward to help the French. He refers first of all to the Scottish Women's Hospitals, where a staff of eighty nurses have been maintained for three years, and mentions that Miss Ivens, the *médecin-chef* of the hospital at Royaumont, has recently been decorated with the Legion of Honour. Nurses for other units have been provided by the Russian Red Cross, by a Swiss nursing school at Lausanne, by Italian organizations on the Riviera, and by Spanish organizations at Biarritz.

THE Board of Agriculture has reissued, after revision, a leaflet on jam making in war time. The chief novelty to housekeepers in it is the recommendation to replace one-third of the sugar ordinarily used by glucose (corn syrup or glucose chips, sold retail at 7d. or 8d. per lb.). Directions for making jam with glucose alone are also given. The liquid glucose gives the jam a superior flavour to that prepared with glucose chips, but the objection to both is that they are not so sweet as sugar. It is suggested that this may be remedied by adding a small quantity of saccharine. Copies of the leaflet can be obtained free on application to the Secretary of the Board, 3, St. James's Square, London, S.W.1.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are (1) *EDITOR* of the *BRITISH MEDICAL JOURNAL*, *Aitology, Westrand London*; telephone, 2631, Gerrard. (2) *FINANCIAL SECRETARY AND BUSINESS MANAGER* (Advertisements, etc.), *Articulate, Westrand London*; telephone, 2630, Gerrard. (3) *MEDICAL SECRETARY*, *Medisera, Westrand London*; telephone, 2634, Gerrard. The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

ANSWERS.

DR. FRED. H. HAYNES (Leamington) writes: In answer to "W. M. B." (*BRITISH MEDICAL JOURNAL*, August 25th, p. 276), I would recommend him to try mercury either by inunction or hydr. creta gr. 3 to gr. j three times a day. It is not generally recognized that epilepsy is usually due to syphilis (inherited), and that mercury in children is almost a certain cure, and often, too, if epilepsy begins at puberty.

LETTERS, NOTES, ETC.

A TOO-PUNGENT MOUTH-WASH.

MR. EDMUND BALDING, L.D.S. (London, S.W.), writes: From clinical observation extending over twenty-five years I can emphatically confirm Mr. J. T. Hall's assertion that highly pungent washes, powders, and pastes are a source of marginal gingivitis. I will even go further, and say that they are a cause of a peculiarly aggravating and distressingly sensitive form of interstitial caries. I make it a rule to question patients suffering from such as to the prophylactic measures employed, and more frequently than not I receive the reply that a carbolic dentifrice is regularly used. Indeed, such a question is often anticipated by patients volunteering the information, in an injured tone that they "cannot understand why there should be such an amount of caries when they use carbolic tooth-powder twice a day." Some years ago a chemist showed me a sample of carbolic tooth-powder of his own compounding for which he had a large demand, which he attributed to the large percentage of carbolic acid in it.

KILTS AND DECENCY.

DR. ROBERT CRAIK (Ealing) writes: On boarding a tram at Hammersmith to go out to Fulham last Saturday afternoon it happened that I followed upstairs a soldier of the London Scottish. Looking up as I came to the turn on the stair, I was astonished to have a full view of the soldier's buttocks with the testicles dangling down. Is this considered full dress for the regiment?

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

British Medical Journal.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

LONDON: SATURDAY, SEPTEMBER 8TH, 1917.

EDUCATIONAL NUMBER, SESSIONS 1917-1918.

THE PROFESSION OF MEDICINE.

THE main object of this issue of the *BRITISH MEDICAL JOURNAL* is to meet the needs of two classes—those who require information as to the course which must be followed in order to become a legally qualified practitioner of medicine, and those who, having already attained this position, are doubtful as to what particular part in medicine they should choose as a career after the war.

In the United Kingdom the conditions with which those who desire to enter the medical profession must comply are regulated by a statutory body known as the General Medical Council, and a statement of its requirements will be found on page 311. The task of examining candidates as to their fitness to practise medicine is left to the universities and to certain corporations in England, Scotland, and Ireland. But the Council takes steps to ensure that the tests imposed do not fall below a certain standard, and that none of these bodies admits to its examinations persons who have not undergone certain definite courses of instruction at a recognized medical school.

Successful candidates at such examinations eventually receive from the body holding them either degrees, in the case of the universities, or diplomas or licences, in the case of the corporations, entitling them to claim insertion of their names in the *Medical Register* kept by the General Medical Council. At one time the holders of diplomas and licences formed the great majority of all medical men, especially in England and Wales, but of recent years universities have greatly multiplied. Consequently so many practitioners now hold degrees that, save in exceptional circumstances, the wisest course for a medical student is to aim at a degree, though it may be desirable to take also a diploma or licence.

Apart from the degrees and diplomas and licences, on the strength of which the General Medical Council admits to the *Medical Register*, most of the bodies in question bestow on candidates who have passed further examinations higher titles, such as "Fellow" and "Doctor of Medicine." It may be said that as a rule they are worth obtaining, though the difficulty of doing so, and the added professional status they confer, vary considerably. There are also a certain number of diplomas in special branches of work, such as public health and tropical medicine, which are superfluous in the case of most medical men, but either useful or indispensable for those who wish to specialize in the work covered by them.

The expenditure involved in successfully completing a medical curriculum varies so much that no single precise statement on the subject can well be made. Apart from differences in the charges made by different medical schools for instruction, there are differences also in the fees for examination, as well as in those charged for the actual certificates given to

successful students. Besides this, not all students, however industrious, get through examinations with equal facility. Since in any case their professional education must continue for at least five years—a period exceeded by the vast majority—and since the cost of living in different parts of the kingdom varies much, and personal expenditure varies still more, it can only be said that no one should think of entering the profession who is unprepared to spend on his medical education about £1,000.

When once a medical graduate, diplomate, or licentiate has obtained the insertion of his name in the *Medical Register* there are many courses open to him. He can aim at becoming a general practitioner; or at entering one of the Government services at home or abroad; or at specializing in public health or asylum work, or in pure science, or in one or other of the many modern subdivisions of medicine and surgery. Most of these different paths in medicine are considered in detail elsewhere, but a few observations may here be made as to the first and last of them.

A man becomes a general practitioner either by taking a house and waiting for patients to seek his services, or by entering into partnership with some already established practitioner. The successful conduct of a private practice demands, however, a great deal of knowledge other than that acquired at the medical schools, and consequently no man is likely to be accepted as a partner, or to prove successful as an independent practitioner, unless he has first gained experience in private practice as an assistant.

The path of those whose ambitions lie in the direction of becoming consultants or specialists is rugged. Their eventual success will depend not only upon their mental attainments and capacity for hard work, but on their possession of the various qualities which help to win for a man the confidence both of his colleagues and of the general public. Moreover, since it is certain that, however well equipped they may be, they will not for many years make as specialists enough to pay their outgoings, this path is only open to those with sufficient means to maintain themselves for an indeterminable number of years, or who are able, by teaching or in other ways, to make sufficient to defray their expenses.

It is not the purpose of this number to put forward any opinion as to what paths in medicine offer the greatest attractions, whether financial or scientific. Whatever the branch of medical or surgical practice chosen, it must be remembered that the large majority of medical men make but a moderate income. The financial returns of even the most successful practitioners compare but ill with those obtained by persons of equal ability in other walks of life. The Insurance Acts stand for a movement that has done much to convert the general practitioner who is on the panel into a part of a piece of official mechanism,

but nothing to maintain or improve the status of the medical profession, unless it be by the increased opportunities for scientific work afforded by the Medical Research Committee established under the Act of 1911. The full effects of the National Insurance scheme on the profession cannot yet be estimated, for, in spite of modifications by many hundreds of successive orders, circulars, and regulations, it is still far from having reached any stable form.

The effects of the war upon the medical profession, and more especially upon medical education, have, of course, been profound and far reaching; it will suffice to indicate a few of them briefly in this place. It was stated in Parliament last year that the Army and Navy together were employing the services of more than 12,000 medical men, and owing to the increasing demands of the army this figure must now be considerably greater. For comparison we may point out that before the war some 3,300 medical officers were accredited to the Services year by year in the *Medical Directory*. Further, a great many practitioners in civil practice are devoting a share of their time to attendance at military hospitals of various kinds; while medical recruiting boards employ a considerable number of civilian doctors. From all this it is evident that the civilian population must be dispensing with a large part of the medical attendance it receives in normal times, while many, if not all, of the civilian practitioners at home are very hardly worked. The searching investigations of the statutory professional bodies engaged in selecting civilian doctors for the army and safeguarding the medical needs of the civil community have shown that there are now scarcely any areas from which further doctors can safely be taken under existing conditions and powers. A communication pointing out this serious state of affairs has, therefore, been forwarded to the Government.

The effect of the war upon the number of medical students in their different years of professional study has been described from time to time by Sir Donald MacAlister in his presidential addresses to the members of the General Medical Council. Between the years 1910 and 1914 the annual entry of first year medical students averaged roughly 1,440. Since the war the number of these entries has increased by several hundreds a year. At the request of the Director of Recruiting, Sir Donald MacAlister obtained this year from the deans and registrars of medical schools in the United Kingdom a return of the number of students actually pursuing medical studies in January, 1917. This return showed that while in May, 1916, the whole number of medical students was 6,103, including 1,379 women, in January, 1917, the whole number was 6,682, including 1,735 women. This increase was, of course, mainly in the first and second years; the fourth and final years taken together were stationary. The third year, which, according to calculations, will supply most of the newly qualified practitioners of 1919, numbered in January last only 572 men and 261 women. Since February, however, a fresh call by the War Office for the combatant ranks, extending to one group of medical students not classified as fit for general service, has had the effect of reducing the above numbers. It is now clear that certainly in 1918 and 1919, and probably in the present year, a serious shortage of newly qualified medical practitioners must be expected. On the other hand, owing to the larger entries into the medical schools during the past two or three years, an increase in the number of registered practitioners, both men and women, may be expected in the years 1920 and 1921. All these facts have been placed before the military authorities,

and in his address last May Sir Donald MacAlister acknowledged that they had received from the Director of Recruiting (Sir A. C. Geddes) the consideration which might be expected from an officer himself familiar with the requirements of medical education. From replies to questions in the House of Commons by the Under Secretary of State for War it appears that the present policy of the War Office is not to call up medical students if they are within twenty-four months of qualifying, provided they are enrolled in an officers' training corps; while fourth and fifth year students already serving in the combatant ranks are to be released in order to complete their medical studies. An Army Council instruction of December 8th, 1916, laid down that *bona fide* medical students below category "A," and fourth and fifth year men of all categories were to be relegated to the reserve and required to return to their professional studies and enrol in an officers' training corps.

Another feature of the last three years has been the great increase in the number of women going in for the study of medicine. For this the war must be held largely responsible. As for the professional instruction of these large numbers of medical students, men and women alike, there can be no doubt that the war, by diverting the activities of many of their teachers into other channels or other spheres, has considerably depleted the teaching staffs of the hospitals and other educational institutions in which the preliminary subjects and various branches of medical science are taught. Nevertheless, the teachers who continue at their posts are making every effort to maintain the standard of instruction; and, in spite of war-time difficulties, it may be said that now that the Board of Education is gradually assuming a larger share in the general direction of medical studies, the educational prospects of the medical student should show a steady improvement year by year.

What will be the prospects of the medical profession when the war is over? The medical services have acquitted themselves extremely well in the war, and medical science will come out of it with an enhanced reputation. Surgery has made considerable advances, the treatment of wounds has improved greatly, orthopaedic treatment for the crippled and maimed is more successful than ever; preventive medicine in camp and trenches has, with but few exceptions, scored far greater triumphs than could ever have been expected; the work of the pathological laboratory and of the bacteriologist has proved to be of the utmost value. In civil life the spirit of the times is all in favour of extension and co-ordination of the public health services. This is reflected in the widely-supported proposal for the setting up of a Ministry of Health. In the near future more medical care will be provided for expectant mothers, for infants, for children, and for the victims of certain diseases; a great increase in the public work of pathological laboratories all over the kingdom may be confidently expected. All this means an increase in the official medical services. What fate is in store for the private practitioner we will not venture to prophesy. Before the war his position had been profoundly affected by the Insurance scheme. It has converted the majority of general practitioners into part-time civil servants, and subjected them to the discipline of Insurance Commissioners. Pecuniarily it has benefited some and impoverished others. Many believe that the State will gradually tighten its grip on the medical profession.

Finally, it should be noted that a quality every medical man should possess is a strong sense of *esprit de corps*. Medicine, like the Church, is a

profession which the general public—as also public authorities—persistently regards as being of a semi-philanthropic character. Furthermore, it is a profession whose aims and requirements are very ill understood by persons who have not undergone a medical education. Consequently the interests of the medical profession, both on its financial and scientific sides, are continually being attacked, sometimes openly, sometimes insidiously. For this reason it is absolutely essential that medical men should band themselves together for the common protection of themselves and the profession that they represent, and to this end join the British Medical Association¹ as soon as they have entered their names on the *Medical Register*. For the objects of this body are to promote the progress of medical science and the interests of the medical profession, and its past history shows that it has well fulfilled them.

THE GENERAL MEDICAL COUNCIL.

THE General Medical Council is a body which was called into existence by the first Medical Act of 1858. A certain number of its members are elected by the medical profession, and the rest—who form the great majority—are nominated by Government itself and by the universities and such medical corporations of the United Kingdom as have a statutory right to issue diplomas. Its head quarters are at 44, Hallam Street, Portland Place, W.1, and it has branch offices at 54, George Street, Edinburgh, and 35, Dawson Street, Dublin. Its duties are to control the medical and dental professions in the interests of the general public, and to that end to maintain a register of legally qualified practitioners. It is admission to this *Register*, and not the possession of a medical degree or diploma, that constitutes a person a legally qualified practitioner. The Council is bound to admit to the *Register* those who hold the degrees or diplomas granted by the bodies represented among its members, but it can prescribe the terms on which those bodies shall grant such diplomas or degrees, and it can erase from the *Register* the name of any medical man or dentist who has been convicted before a court of law of an ordinary crime or of a serious offence against public morality, or who is proved before the Council itself to have been guilty of certain actions which the Council regards as professionally infamous. Its disciplinary powers are strictly limited to legally qualified practitioners, and it has no control whatever over irregular practitioners of any kind.

An account of the regulations that the Council has drawn up in respect of the education of medical students here follows. The primary important things to note about them are that they entail (1) the production of proof of a certain degree of proficiency in subjects of preliminary or general education; (2) application for registration as a medical student either at the head quarters office in London or at one of the branch offices in Edinburgh and Dublin, although this latter requirement is not invariably enforced.

PRELIMINARY EDUCATION.

The regulations with regard to the subjects of the preliminary examinations recognized by the Council have been modified since our last Educational Number. At a meeting of the Council in November, 1916, the question of Latin as a compulsory subject in the preliminary examination in general knowledge for medical science was brought to a point. The Education Committee recommended in its report that in the matriculation examinations for the faculties of arts and science, and equivalent examinations, the Council should no longer regard Latin as a compulsory subject. For practical purposes the recommendation was that all examinations accepted for matriculation in the

faculties of arts and science in any university of the United Kingdom should be approved by the Council as qualifying a successful candidate for admission to the *Students' Register*. This carried with it the recognition of degrees in arts and science of any university of the United Kingdom or of the British Dominions. The recommendation, which applied only to the senior or higher grade student, was accepted by the Council. So far as the junior or lower grade of candidates are concerned, the Education Committee, as a matter of expediency rather than of logic, proposed that Latin should remain compulsory for these candidates, since they do not, as a rule, produce as evidence of general knowledge certificates of examination by a university.

The lists of educational bodies whose examinations are now accepted under the regulations made by the Council for the maintenance of the register of medical students, together with other particulars, are published with the *Students' Regulations*, which may be obtained from the various offices of the Council, price 6d.

REGISTRATION OF MEDICAL STUDENTS.

In addition to showing that he has passed one of these examinations, any person applying for registration as a medical student must (1) produce satisfactory evidence that he has attained the age of 16 years; (2) show that he has commenced medical study at a university or school of medicine, or at a teaching institution recognized by one of the licensing bodies and approved by the Council. The commencement of professional study will not be reckoned as dating earlier than fifteen days before the date of registration.

Application for registration should be addressed to the Registrar for the division of the United Kingdom in which the applicant is residing—England and Wales, or Scotland or Ireland. It must be made on a special form, which can be obtained on application at the offices either of the General Medical Council itself or of one of the various licensing bodies and medical schools, and when forwarded it should be accompanied by the certificates as to age and general education.

The regulations with regard to registration apply equally to medical and dental students, with the exception that in the case of the latter pupillage with a registered dental practitioner may be regarded as a commencement of professional study, and that applications for registration should be addressed to the London office only.

PROFESSIONAL EDUCATION.

The rule is that it is only from the date which appears against his name in the *Students' Register* that the medical student's career officially begins: thereafter five years must pass before he can present himself for the final examination for any diploma which entitles its lawful possessor to registration as a qualified medical practitioner under the Medical Acts.

There are, however, certain important exceptions to this rule: thus (1) to meet the circumstances brought about by the dates at which sessions of the medical schools commence and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. (2) Graduates in arts or science of any university recognized by the General Medical Council, who have spent a year in the study of physics, chemistry, and biology, and have passed an examination in these subjects for the degrees in question, may be held to have completed the first of the requisite five years. (3) The Council will accept as six months of that year six months passed, subsequent to obtaining a certificate in general education, as a student of chemistry, physics, or biology at any teaching institution recognized by a licensing body and approved by itself. In any case, the period of five years must be one of bona fide study, and during its course education in the following subjects must be pursued and examinations passed:

- (i) Physics, including the Elementary Mechanics of Solids and Fluids, and the rudiments of Heat, Light, and Electricity.
- (ii) Chemistry, including the principles of the science, and the details which bear on the study of medicine.
- (iii) Elementary Biology.
- (iv) Anatomy.
- (v) Physiology.
- (vi) Materia Medica and Pharmacy.
- (vii) Pathology.

¹The ordinary subscription of members resident within the United Kingdom is £2 2s., but as from January 1st, 1915, those admitted within two years from the date of their registration pay only 25s. until the expiration of four years from such registration. Members resident outside the United Kingdom pay 25s. to the parent Association.

- (viii) Pharmacology and Therapeutics.
- (ix) Medicine, including Medical Anatomy and Clinical Medicine.
- (x) Surgery, including Surgical Anatomy and Clinical Surgery.
- (xi) Midwifery, including Diseases peculiar to Women and to Newborn Children.
- (xii) Theory and Practice of Vaccination.
- (xiii) Forensic Medicine.
- (xiv) Hygiene.
- (xv) Mental Disease.
- (xvi) Anaesthetics.

The practical study of Subject (xi) shall not commence until the student has held the offices of Clinical Clerk and Surgical Dresser, and the work done in connexion with it must follow prescribed lines. The Council also expects that study of the Subjects (vii) to (xvi) shall extend over not less than twenty-four months subsequent to success at the examination in Subjects (iv) and (v). It also now recommends licensing bodies to require of candidates at their final examinations evidence of instruction in the administration of anaesthetics and in infectious diseases, and of sedulous attention in hospital wards, out-patient departments, and *post-mortem* rooms, as clerks and the like.

Wherever the first of the five years is spent, the next three must be passed at one of the schools of medicine recognized by any of the licensing bodies enumerated in the schedule of the Medical Act of 1858. The final or fifth year the Council recommends should be devoted to clinical work at any public hospital or dispensary at home or abroad which is recognized by any of the licensing bodies.

SPECIAL CONSIDERATIONS.

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in outline, but before leaving this part of the subject the steps which the aspirant should take may finally be rehearsed in their due order:

- (1) Pass an examination in arts;
- (2) Enter himself at a medical school or other scientific institution recognized by the Council;
- (3) Get himself registered as a medical student;
- (4) Study for a minimum of five years certain prescribed subjects;
- (5) Meanwhile pass sundry intermediate examinations; and, finally, at the end of the fifth year, one which will entitle him to receive at the hands of a licensing body a legal authority to practise.

The Arts Certificate.—There are, however, other important considerations; thus, it is not a matter of indifference what certificate of proficiency in general education, or arts, the student obtains. The General Medical Council, it is true, will accept any of the large number of tests to which reference has been made, and this, too, is the case with practically all the college corporations in England, Scotland, and Ireland. But all the licensing bodies are not equally accommodating; some of the universities require that their own ordinary matriculation should be passed, others have special matriculation examinations for those wishing to join their medical faculty, and a third and larger number will accept any arts degree and certain matriculation examinations, as well as several other of the tests entered in the Council's list.

The first thing, therefore, the future medical student should, if possible, decide is at what degrees or diplomas he intends to aim, and then find out what arts certificate will be required. If he cannot decide the question in advance, the best course probably would be to matriculate at London University. It is a troublesome examination in many respects, but gives a wide choice of subjects, and has the advantage of being accepted as sufficient testimony to general education by a larger number of bodies than is any other analogous examination.

The Minimum Period.—Another point to remember is that the period of five years mentioned is a minimum; a good deal more will almost certainly be required even by the man of good abilities and reasonable industry. Besides these qualities, a student to obtain a registrable qualification in the minimum period of five years, or fifty-seven months, must have a considerable amount of good luck; in other words, he must keep in good health through every term, and never fail at a single examination. Otherwise

it is almost inevitable that his career as a student should be prolonged for a greater or smaller number of months beyond the possible minimum. Thus, for instance, a student before presenting himself for any examination has to get what is called "signed up" for the subjects covered by that examination; this means that his teachers have to certify that he has attended the required number of lectures or classes in the subjects in question. If, however, the student happens to be ill during the term when such lectures or classes are taking place, he may miss a sufficient number of them to make it impossible for him to be "signed up." Then, again, should a student fail to satisfy the examiners at some examination, he cannot present himself again for re-examination for at least three months. This fact generally entails further consequences, because, apart from the student's success at the next stage in his career being imperilled by his having to give up some time to restudying the subjects in which he has failed, the Examining Boards in the majority of instances insist upon a definite interval elapsing between a student passing one examination and his presenting himself for that which should follow it. Then, again, many Boards refuse to recognize lectures and classes which have been attended at a date anterior to that at which the student has passed the requisite examination in earlier subjects. Failure at an examination may thus not only mean deferment of the date of examinations, but deferment of the commencement of the student's study of certain subjects. It is thus exceedingly easy for a student to fail to qualify in five years, and as a matter of fact, the vast majority of students take very much longer than that period.

Furthermore, in speaking of the minimum period, it is to be remembered that that time is only sufficient to gain a registrable qualification, such as a Bachelorship of Medicine or Surgery or a diploma of one of the Royal Colleges. These are quite sufficient for the purposes of general practice, or for entering the Services, etc., but those who wish to take a higher qualification—for instance, the F.R.C.S. Eng.—must prolong their work for another year or more. So, too, must in some cases those who desire to convert their Bachelorship into an M.D. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age, and has practised his profession for a certain number of years. However, a student's career proper may be considered, perhaps, to have ended at the time he obtains his first registrable qualification, for while preparing himself for any further tests he can, and usually does, hold some junior appointment which more or less covers his expenses.

The Normal Course.

In conclusion, it may be convenient to sketch the general fashion in which the student will pass his five years or more, but discussion of this need not be prolonged, because once a student has entered at a school, and chosen the degrees or diplomas at which he wishes to aim, the dean of the school will guide his steps in every particular.

Whatever the precise final goal, the path thereto is in all cases identical in broad outline. Practically it is divided into three stages, the conclusion of each being marked by an appropriate examination. In the first stage the student acquires a more or less extensive knowledge of the preliminary sciences—chemistry, physics, and biology; in the second he studies anatomy and physiology; and the third he devotes to the real work of his future life—medicine and surgery and their branches. During each of these stages the student must attend not less than the prescribed number of lectures and classes to ensure getting "signed up" in the subjects of the stage, and also do a very considerable amount of practical work. As for the examinations at the end of the stages, these are known by different titles by different examining bodies, but "preliminary science," "intermediate," and "final" are in common use. Some bodies demand that the student should pass in all the subjects of one stage at one time; others allow the candidate to present himself in each of the subjects separately, thus multiplying the actual number of examinations, but limiting their scope. There are also differences in the requirements of the different licensing bodies as to the length of each stage, but practically all demand that the second shall be longer

than the first, and the third not shorter than the second. By the length of the allotted stage the candidate may gauge the comparative importance the licensing body attaches to the subjects within the stage and the difficulty of the tests it will impose, and he may feel certain that the time allotted is none too much.

In any case it should be the aim of the student to get through his first two stages as quickly as his abilities and the regulations will allow; and, as a rule, he should have completed the first stage by the end of his first year, and may hope to complete the second stage not later than the end of his third year. He will then have two years in which to prepare for his final examination, and it will prove a very crowded period, for he has to get into it not only medicine, surgery, and midwifery proper, but many other allied subjects, such as pathology and bacteriology, forensic medicine, gynaecology, and therapeutics. In the first of the final two years he may be able to complete his formal lectures, and thus have the fifth year for entirely practical work and private study; during those two years, too, he will take part in the work of his hospital by holding clerkships and dresserships in the wards and out-patient department for the periods laid down by the licensing bodies. Then, at length, after perhaps a few weeks of special coaching, he will be ready to present himself for his final examination, which the regulations of most bodies will allow him to divide into two or more parts. The final examination passed in its entirety, he will be able to claim registration as a qualified medical practitioner at the hands of the General Medical Council, and become an independent personage. There is still room for him to continue a student's career if he will, for, apart from the higher qualifications to which reference has been made, it may seem to him worth while to devote time to acquiring greater knowledge of some particular branch of medicine, such as ophthalmology or laryngology, or to undergo the courses of study necessary to obtain a diploma of special proficiency in questions of public health (page 341), or in tropical medicine (page 340). Points such as these, however, the student will be fully capable of deciding for himself when he has reached the stage to which our account has now brought him.

The next matters to be considered, therefore, are the requirements in detail of the different licensing bodies, and what they have to offer in the way of degrees and diplomas.

THE WAR.

The Council advised the licensing bodies that its recommendations respecting the courses of medical study represent, in general terms, the minimum curriculum that should be required by the various licensing bodies. But it recognizes that during the present national emergency it may be advisable for them to modify or even suspend their regulations. It feels sure, however, that the licensing bodies concerned will recognize the importance, in the public interest, of maintaining unimpaired the present standard of knowledge and skill required of all who seek to be admitted to all the status and privilege of registered practitioners. It will therefore be desirable to secure in every instance that the requirements of the minimum curriculum are to be substantially fulfilled. The standard of the qualifying examinations, in other words, is to be maintained.

The English Universities.

THERE are eleven universities in England and Wales, and some account of each of them follows. With one exception they all have fully developed medical faculties. The exception is the University of Wales, whose constituent colleges are those of Aberystwith, Bangor, and Cardiff. It is in a position, however, to grant degrees, and has laid down a six years' curriculum for candidates for the M.B. degree, and it already provides, at the School of Medicine at Cardiff—of which an account will be found at page 331—thorough training in the work of the first three or four years.

UNIVERSITY OF OXFORD.

THE professional degrees conferred by this university are those of Bachelor of Medicine (B.M.), Bachelor of Surgery (B.Ch.), Doctor of Medicine (D.M.), and Master of Surgery

(M.Ch.). It also grants a diploma in State Medicine and a diploma in Ophthalmology. On receiving the B.M. the candidate is entitled to registration by the General Medical Council. In favourable circumstances this degree and the B.Ch. may be obtained in six or seven years from matriculation. Before receiving either, however, the candidate must have taken a degree in Arts (B.A.), for which three years' residence within the university is necessary. This, however, does not necessarily mean deferment of professional study for that period; for some of the subjects chosen for the final stage of the arts course may be the same as those in which examinations would in any case have to be passed for the medical degrees.

THE B.A. DEGREE.

A candidate may obtain the B.A. degree in either of the following ways:

(a) By passing Responsions (or one of the examinations which are accepted as equivalent), Moderations, a Scripture examination, or, in the event of a candidate objecting, an examination in some substituted book; and the Final Pass School in three subjects, two of which may be the same as two in the preliminary examinations in natural science.¹

(b) By passing Responsions, an additional subject in Responsions, the Scripture examination, some of the preliminary examinations in the Natural Science School,¹ or the Preliminary Examination and the School of Jurisprudence, or the Honour School of Mathematics in the first public examination; and one of the final honour examinations.

Responsions and the additional subject may be passed before a candidate is a member of the university;² Moderations and Scripture can be passed in or after the second term; the final pass school may be taken any time after Moderations; a final honour school may be taken at the end of the third or within the fourth academical year—that is, twelve or sixteen terms respectively; the preliminary examinations of the Natural Science School may be taken as soon as Responsions have been passed.

PROFESSIONAL DEGREES.

To obtain the B.M., B.Ch. degrees the candidate must first pass in four of the subjects of the Preliminary Examination of the Natural Science School—namely, physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First M.B. and the Second M.B. These take place twice a year, the first on the Thursday, the second on the Wednesday, of the eighth week of Michaelmas and Trinity terms. Every candidate at the First M.B. is examined in human anatomy and also in physiology and in organic chemistry, unless he has previously taken a first or second class in the two latter subjects in the Natural Science School. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pleases in pathology, forensic medicine, and hygiene, materia medica, and pharmacology³ (subjects of the second examination), but cannot present himself for the remaining subjects—medicine, surgery, and midwifery—until the twenty-fourth term from the date of his matriculation, and not until a period of at least twenty-two months have elapsed from the date of his passing the first examination, and he must take all the three subjects at one and the same time.

D.M. AND M.Ch. DEGREES.

A Bachelor of Medicine who wishes to proceed to the M.D. must have entered his thirty-ninth term and must present a dissertation for approval by the appointed examiners. If a candidate for the M.Ch., he must have entered his twenty-seventh term and must pass an examination which is held in June.

TEACHING.

The several colleges provide their undergraduate members with tutors for all examinations up to the B.A. degree.

¹ The four subjects of the medical preliminary examinations are four of the subjects in the natural science preliminary, and can be commenced directly after passing Responsions.

² Membership is constituted by matriculation and by becoming either a member of a college or hall, or a non-collegiate student.

³ A candidate who passed in materia medica and pharmacology under the old regulations in the First Examination before April 14th, 1909, is exempt from the examination in materia medica and pharmacology in the second examination.

In addition, the university provides certain courses of instruction, including lectures, demonstrations, and practical work, which cover all the subjects of the Preliminary Examination and First M.B., and in part those of the Final Examination. For the diploma in State Medicine and the diploma in Ophthalmology certain of the courses can be taken in Oxford.

SCHOLARSHIPS.

The several colleges grant scholarships of £80 a year, tenable for four years, in natural science, chemistry, physics, and biology. Exhibitions of varying value are also awarded in these subjects. Particulars can be obtained on application to the college tutors. A Radcliffe Travelling Fellowship of £200 a year, tenable for three years, is conferred annually; candidates must have taken the B.M. degree. A Philip Walker Studentship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of research in pathology, as also are the Rolleston Memorial Prize, for research in natural science (including pathology), and the C. Theodore Williams Scholarships in Anatomy and Physiology, and in Pathology, of the value of £50 each, tenable for two years. A Burney Yeo King's College Hospital Scholarship of £80 is awarded annually.

FEES.

An annual fee of £2 10s. is paid to the university for the first four years, being reduced to £1 when the B.A. has been taken. For the degree the fees are—the B.A., £7 10s.; the B.M. and B.Ch., £14; the D.M., £25; the M.Ch., £12. College fees, varying in amount, are paid for the first four years of membership and in taking degrees. Tuition fees vary from £21 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £120.

UNIVERSITY OF CAMBRIDGE.

THE professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.C.), which entitle the possessor to admission to the Register by the General Medical Council, and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants diplomas in Tropical Medicine and Public Health to persons who are registered medical practitioners, but not necessarily graduates of the university.¹ A candidate for the M.B., B.C. degrees need not possess a degree in arts; it is sufficient if he has passed the *Previous examination* or some other examination accepted by the university as its equivalent.

PROFESSIONAL EXAMINATIONS.

To obtain the M.B. the candidate must pass three examinations of which the latter two take place twice a year, in the Michaelmas and Easter terms; those who are finally successful receive the B.C. degree without further examination.

First M.B. or Preliminary Examination in Science.—This comprises (1) chemistry, (2) physics, (3) elementary biology. The parts may be taken together or separately. In either case the candidate before admission to examination must have satisfied the requirements in respect of the *Previous examination*, paid the matriculation fee, and entered on his first or some later term of residence. During the continuance of the war students may be admitted to this examination though they have not commenced residence. The other requirements must be satisfied. The examination is held three times a year—in October, December, and June.

Second M.B.—This examination, which cannot be passed until the first examination has been completed, comprises Part I, human anatomy and physiology; Part II, elementary pharmacology, including pharmaceutical chemistry and the elements of general pathology. No one may enter Part II unless he has passed Part I. The candidate must be signed up in both subjects and have dissected for six months.

Third M.B.—This is divided into two parts, to neither of which is the candidate admitted until he has passed the examinations previously mentioned. A candidate for the first part, which deals with surgery and midwifery, must have completed five years of medical study and be signed up in these subjects and have completed two years of hospital practice.

Before admission to the second part the candidate must have completed five years of medical study and be duly

signed up in all subjects and have completed three years of hospital practice. He must also possess certificates showing that he has fulfilled all the recommendations as well as the requirements of the General Medical Council. The examination is in the principles and practice of physics, pathology, and pharmacology.

Act for the M.B.—Before receiving his degree, a candidate who has been successful at the Final M.B. has to write a thesis. This he reads in public on an assigned day, and is then questioned concerning it and other subjects of medicine by the Regius Professor of Medicine. If approved at this test he is then certified as having "kept the Act" satisfactorily, and in due course receives his degree. Medical degrees may be taken in absence, the candidate sending a thesis to the Regius Professor of Physic, which is laid before the Board.

THE HIGHER DEGREES.

The M.D. degree may be taken by an M.B. of three years' standing after keeping a further Act and writing a short extemporary essay, in which he may deal at his choice with either medicine, physiology, pathology, or State medicine. The M.C. degree may be granted to a candidate who has qualified for the B.C. at least three years previously; he is then examined in pathology, surgery, surgical anatomy, and surgical operations, or submits books or writings of his own which constitute original and meritorious contributions to the science and art of surgery.

FEES.

In addition to college fees, tutorial fees, and the expenses of living, the following examination fees are payable: First M.B., £4 4s.; Second M.B., £4 4s.; Third M.B., £9 9s. For schedules referring to the examinations, lists of schools recognized by the university, and other information, application should be made to the University Registry.

UNIVERSITY OF LONDON.

UNDER the regulations of the University of London, the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Surgery, Mastery of Surgery in two branches, and Doctor of Medicine in six different branches. The university has its own matriculation examination, and this is of so peculiar a kind that candidates should secure and carefully study the booklets relating to it.

In no circumstances is a degree granted to any one in less than three years after the date at which he passed the Matriculation Examination or obtained registration in some other way; and unless they are already registered medical practitioners of a certain age and standing, all students must pass not less than five and a half years in professional study subsequent to matriculation. Four and a half of those years must be passed at one or more of the medical institutions or schools at home or abroad recognized by the university for the purpose; and not less than one in a school of the university itself.

PROFESSIONAL EXAMINATIONS.

M.B., B.S.—There are three examinations, the last two being subdivided. They are held twice a year.

The First Examination covers inorganic chemistry, general biology, and physics, there being two papers, a practical test, and a possible viva voce test in each subject. The names of successful candidates are placed in alphabetical order, with a note as to any subject in which a candidate has distinguished himself.

The Second Examination, Part I, cannot be passed within six months of the passing of the First Examination. It covers organic and applied chemistry, the candidate's knowledge being tested as in the earlier examination. It is a pass examination, but a mark of distinction may be won.

Candidates for Part II must have passed the First Examination at least eighteen months previously besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and pharmacology, the tests being written, oral, and practical. Candidates who fail in one subject may offer themselves for re-examination in that subject alone if the examiners think fit.

¹ See pp. 340 and 342.

No candidate is admitted to the Third M.B., B.S. Examination within three academic years from the date of his completing the Second Examination. The subjects are medicine (including therapeutics and mental diseases), pathology, forensic medicine and hygiene, surgery, and midwifery and diseases of women. They may be divided into two groups, one comprising medicine, pathology, forensic medicine and hygiene, and the other surgery and midwifery and diseases of women. Either group may be taken first at the option of the candidate, or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but in the list of successful candidates the names are divided into an honours list and a pass list, in each of which the names are placed in alphabetical order, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination.

THE HIGHER DEGREES.

M.D.—An examination for the M.D. is held twice yearly—in December and July. Every candidate must have passed the examination for the M.B., B.S., unless he became M.B. before May, 1904. He may present himself for examination in any one of the following branches: (1) Medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) State medicine, (6) tropical medicine, and, if he wishes, may pass also in another branch at a subsequent examination.

The period that must elapse between acquiring the M.B. and sitting for the M.D. in any branch varies with the nature of the candidate's previous work between one year and two years, and in all cases evidence must be afforded of special study of the subject chosen, whatever the branch; both written and practical examinations must be passed, though exemptions can be obtained from the former in exceptional circumstances. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example, medicine in the case of branch (4), pathology in branch (1)—an essay on one of two suggested topics connected with the special subject, and a clinical or other practical test. In any branch of the M.D. Examination a gold medal of the value of £20 may be awarded.

M.S.—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are only two branches in which it may be obtained—General Surgery and Dental Surgery.

FEES.

For Matriculation: £2 for each entry. First Examination: £5 for each entry to the whole examination. For re-examination in one subject the fee is £2. Second Examination, Part I: £2 for the first and each subsequent entry. Second Examination, Part II: £3 for each entry to the whole examination. For re-examination in one subject the fee is £4. M.B., B.S. Examination: £10 for each entry to the whole examination, and £5 for examination or re-examination in either group. M.D. and M.S. Examinations: £20, and £10 on re-examination.

SPECIAL REGULATIONS IN RESPECT OF THE WAR.

Internal students who have failed at an intermediate or a Final Pass Examination for a First Degree in a Faculty other than Medicine, but who passed in one or more subjects on the last occasion when they presented themselves for such examination, and who have been debarred from presenting themselves for the corresponding Intermediate or Final Examination held between September, 1914, and a date to be determined later by the Senate, by service under the War Office or Admiralty, or by hospital service in connexion with the war, will be credited with the subjects in which they passed on the occasion in question.

In cases in which students, owing to War Service, have been unable to attend a course of lectures given only in alternate years, they will be permitted, if necessary, on the resumption of their work after the war, to count special tuition approved by the authorities of the school or institution concerned in place of attendance at such courses.

Military service during the war will be counted as equivalent to not more than two terms of a course of study in military science for internal students in any one

of the three years over which such course of study would ordinarily extend.

During the continuance of the war, students who have not passed the Second Examination for Medical Degrees in Anatomy and Physiology, but who have completed one year's study after passing the First Examination for Medical Degrees, will be allowed to count not more than six months' service as clinical clerk or not more than six months' service as surgical dresser in a recognized hospital as if they had so passed the examination in question.

UNIVERSITY OF BIRMINGHAM.

This university confers the ordinary medical and surgical degrees—M.B., Ch.B., M.D., and Ch.M., and also diplomas and degrees in State medicine and dentistry. It has a plan, too, by which, extending his study to six instead of five years, the M.B., Ch.B. candidate may become a Bachelor in Science as well. Of the five years' curriculum, the first four must be spent, as a rule, at the university itself, the fifth being passed at any approved school or schools. Occasionally, however, the Senate will reduce the period of enforced residence to three years and exempt from the First M.B. those who have passed elsewhere an examination considered to be its equivalent.

All students in the Medical Faculty must either (1) matriculate in mathematics, in chemistry or experimental mechanics, in the English language and literature and history, a foreign language, and in either another language or an additional science; or (2) show that they have passed elsewhere an examination deemed an equivalent. Subject to certain provisos, the following are at present thus regarded:

(a) The Previous Examination of the University of Cambridge if it includes the "additional subjects." (b) Responsions of the University of Oxford, except in mathematics. (c) The Matriculation Examination of a recognized university. (d) The Higher Certificate of the Oxford and Cambridge Boards. (e) The Oxford or Cambridge Senior Local Examination. (f) The Senior Certificate of the Central Welsh Board.

PROFESSIONAL EXAMINATIONS.

The candidate for the M.B., Ch.B. degrees has five examinations to pass. In the second and final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

First M.B.—This deals with chemistry, physics, and elementary biology; it may be passed before the student commences residence at the university, provided the regulations as to matriculation have been met.

Second M.B.—This deals with anatomy and physiology, and the student must pass in both simultaneously.

Third M.B.—This deals with general pathology and bacteriology, materia medica, and practical pharmacy.

Fourth M.B.—This takes place at the end of the fourth year, the subjects being forensic medicine, toxicology, public health, therapeutics, and special pathology.

Final M.B.—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a *post-mortem* clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, and ophthalmology. In respect to the latter he must show that he has learnt refraction work. He also has to present to the examiners reports drawn up by himself on six gynaecological cases, and certificates drawn up by himself regarding four actual cases of lunacy, and notes respecting two others.

M.D.—An ordinary candidate for this degree must be an M.B., Ch.B. of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch.M. are of the same general character. Subject to certain requirements as regards special research or other post-graduate study,

* The University of Birmingham having joined the Joint Matriculation Board of the Northern Universities, the above matriculation regulations are in force up to October 31st, 1917. After October 31st, 1917, all communications respecting the Matriculation Examination and examinations accepted in lieu thereof should be addressed to the Secretary to the Board, Joint Matriculation Board, 24, Dover Street, Manchester.

graduates of other universities may obtain the M.D. and Ch.M. in the same way as the holders of the Birmingham M.B., Ch.B.

FEES.

The fee for matriculation is £2, and for each of the first four professional examinations the same amount; M.B., Ch.B. degree fee, £8; M.D. and Ch.M. examination, £10 each. For further particulars application should be made to the Dean of the Medical Faculty.

UNIVERSITY OF BRISTOL.

The university grants the following degrees: In medicine and surgery, M.B. and Ch.B., M.D., Ch.M. (the M.D. may be taken in State medicine); in dental surgery, B.D.S., M.D.S. Diplomas in public health (D.P.H.) and dental surgery (L.D.S.) are also granted. Candidates for degrees must pass the Matriculation Examination (or some equivalent examination accepted in lieu thereof; see the Regulations for Matriculation), and study at the university itself for at least three years of the five and a half years' curriculum, two such years being subsequent to the passing of the Second M.B. Examination. The Matriculation Examination comprises five subjects: (1) Mathematics; (2) a language other than English; (3) English grammar and composition; (4 and 5) two subjects at choice, one of which must be a foreign language. It is held in July and September. The winter session opens on October 2nd, 1917.

PROFESSIONAL EXAMINATIONS.

M.B., Ch.B.—There are three examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The first M.B. comprises chemistry, physics, botany, and zoology. The second M.B. comprises organic chemistry, elementary anatomy (Part I), advanced anatomy, physiology (Part II). The two groups may be taken separately or together. The Final Examination includes materia medica and pharmacy, pharmacology, and therapeutics, general pathology, morbid anatomy and bacteriology (Part I), special pathology, forensic medicine, toxicology and public health, obstetrics (including diseases of women), surgery (systematic, clinical, practical, and operative), medicine (systematic, clinical, and practical), including mental diseases (Part II). The two groups may be taken separately or together. At the option of the candidate, forensic medicine and toxicology may be taken either with Group I. or Group II. First or second class honours may be obtained by a candidate whose work is deemed of sufficient merit, but cannot be awarded to one who has recorded against him a failure at any examination after the First M.B.

M.D.—A candidate for this degree must be an M.B. and Ch.B. of at least two years' standing. He has a choice between presenting an original dissertation, undergoing a general examination in medicine (including medical anatomy, medical pathology and bacteriology, systematic and clinical medicine), or passing an examination in State medicine.

Ch.M.—A candidate must have attended, since becoming M.B., Ch.B., and for not less than two years, a public institution affording opportunity for the study of practical surgery, and produce certificates to that effect; the candidate shall be required to pass a general examination in surgery (including surgical anatomy, surgical pathology and bacteriology, operative and clinical surgery), and to present a dissertation in some department of surgery. He must be of two years' standing as an M.B., Ch.B.

Applications for other information should be addressed to the Dean of the Medical Faculty.

DENTAL DEPARTMENT.

The university grants the degrees of Bachelor and Master in Dental Surgery (B.D.S., M.D.S.) and a Diploma in Dental Surgery entitling to the letters L.D.S. The courses of the university are available equally for these qualifications and for those of other licensing bodies. Both courses are open to men and women alike.

UNIVERSITY OF DURHAM.

To its own graduates, who may be of either sex, this university grants the degrees of Bachelor and Doctor of Medicine (M.B. and M.D.) and Bachelor and Master of Surgery (B.S. and M.S.); it also grants special degrees and diplomas in State Medicine, Psychiatry, and Dental Surgery. To become a graduate, however, at the university it is not necessary to pass the major portion of the five years' curriculum within its precincts, or even to commence that period by matriculation. It is sufficient if, before he presents himself for his final examination, the candidate has passed at least one year in study at the University of Durham College of Medicine, including the practice of the Royal Victoria Infirmary in the same city. The earlier examinations may be passed while the student works elsewhere, but not less than a year must elapse between the date when the student satisfies the requirements of the university as regards matriculation and his presenting himself for the Final M.B., B.S. Examination.

MATRICULATION.

The university has its own matriculation examination, but accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application.

PROFESSIONAL EXAMINATIONS.

There are four professional examinations for the M.B., B.S. degrees. Each is held twice a year—in March and June. The first deals with elementary anatomy and biology, chemistry, and physics; the second with anatomy and physiology; the third with pathology, elementary bacteriology, medical jurisprudence, public health, materia medica, and pharmacy. At the final M.B., B.S., the candidate is examined in medicine and clinical and psychological medicine; surgery and clinical surgery; midwifery and diseases of women and children; clinical and practical gynaecology; therapeutics; diseases of the throat, nose, and ear; diseases of the skin; and diseases of the eye.

M.D.—A Bachelor of Medicine who wishes to proceed to this higher degree must be of at least two years' standing, and satisfy the university that he knows either Greek or German. He then submits a typewritten essay dealing with original work or observations of his own, and is examined in its subject. If the candidate is not an M.B. of the university, he must be a practitioner of fifteen years' standing and submit to special tests.¹

B.S.—A candidate for this degree must have passed the examination for the M.B. of the university, and have attended courses on operative surgery and regional anatomy. He must then perform operations on the dead body before the examiners.

M.S.—Candidates for this degree must, like those for the M.D., satisfy the authorities as to their knowledge of Greek or German, and must have been engaged in practice for at least two years subsequent to becoming B.S. Durham. They are submitted to an examination which covers the whole range of surgical knowledge.

FEES.

The following fees are payable: Matriculation or its equivalent, £1 10s.; First, Second, and Third M.B. Examinations, each £5; Final M.B., £10; M.D., B.S., and M.S., £5 for each examination and £6 6s. for each degree. Further information respecting the examinations and degrees may be obtained from Professor Howden, at the University of Durham College of Medicine, Newcastle-on-Tyne.

UNIVERSITY OF LEEDS.

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.), and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Dental Surgery (M.Ch.D.). It also gives diplomas in public health, psychology, and in dental surgery.

Candidates for the M.B. must have attended courses of instruction approved by the university for not less than five years, two at least of such years having been passed in the university subsequently to the date of passing the

¹ See p. 344.

² See p. 338.

first examination. They must also have matriculated by satisfying the examiners in (1) English (composition and literature); (2) English history; (3) mathematics; (4) three of the following, one of which must be a language: (a) Latin, (b) Greek, (c) French, (d) German, (e) some other modern language approved by the Board, (f) either mechanics or physics, (g) chemistry, (h) geography, (i) natural history or botany. Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., Ch.B. number three. The first deals with (1) physics and chemistry, (2) biology. In each subject laboratory work is included, but the two parts can be taken separately. For neither can the candidate present himself until after matriculation, and at least two or three terms' approved work in the respective subjects indicated.

Second M.B.—This may be taken in two parts: (a) anatomy and physiology, including practical work; (b) materia medica and pharmacy, including actual compounding of drugs. The candidate's certificates must show, among other things, that he has dissected during at least five terms.

Final M.B.—This may be divided into three parts. The first part, pathology and bacteriology, may be taken at the end of the tenth term; the second part, forensic medicine and public health, and the third part, medicine, surgery, and obstetrics, cannot be taken before the end of the fifth year; and before being admitted to the examination in its subjects the candidate, in addition to ordinary certificates, must produce proof that he has done both intern and extern maternity work, and received clinical instruction in gynaecology, in diseases of the eye, skin, or larynx, and in the administration of anaesthetics. This division covers all branches of surgery, medicine (including mental diseases and diseases of children), and obstetrics and gynaecology. Passages for translation from French and German are included in the papers on medicine. First and second class honours may be obtained in this division.

M.D.—A candidate for this degree must be an M.B., Ch.B. of at least one year's standing. He presents a dissertation embodying the results of personal observation or original research, and, if this is approved, passes an examination which consists in the writing of an extemporary essay, and answering questions on the history of medicine and the subject of his dissertation.

Ch.M.—The candidate for this degree must have been admitted to the M.B., Ch.B. not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. In addition, he must have attended certain special courses, including one on ophthalmology and one on bacteriology; he is then examined in the subject of surgery in all its branches.

FEES.

The matriculation fee is £2, and on readmission £1 10s. For each of the other examinations £5, and £2 on re-admission. On conferment of the degree of Ch.M. £5 is payable, the same remark applying to the M.D. degree.

UNIVERSITY OF LIVERPOOL.

This university, besides granting degrees in medicine (M.B. and M.D.) and in surgery (Ch.B. and Ch.M.), gives a degree in dental surgery (B.D.S.), a degree in hygiene (M.H.), and degrees in veterinary science (B.V.Sc., M.V.Sc., and D.V.Sc.). Diplomas are awarded in dental surgery (L.D.S.), tropical medicine (D.T.M.), public health (D.P.H.), veterinary science (D.V.H.), and in several single subjects.

MATRICULATION.

The Matriculation Examination is governed by the Joint Matriculation Board, 24, Dover Street, Manchester, which accepts under certain conditions the tests of several other bodies as its equivalent. These include the Matriculation of London University, the Senior Local Examination of Oxford and Cambridge, the Higher Certificate of the Joint

Oxford and Cambridge Board, Responsions of the University of Oxford, the Previous Examination of the University of Cambridge, the Leaving Certificate of the Scottish Education Department, and the Senior Certificate of the Central Welsh Board. Of the five years' curriculum, not less than two must be passed in the university itself, one such year being subsequent to the date of passing the First M.B. Examination.

PROFESSIONAL EXAMINATIONS.

Candidates for the M.B., Ch.B. degrees have three examinations to pass, the first including (1) chemistry, inorganic, organic, and physical; (2) biology, including zoology and botany; (3) physics. Section 2 may be taken alone or in conjunction with Sections 1 and 3.

Second M.B.—This test covers (a) (1) anatomy, (2) physiology, including physiological chemistry and histology; and (b) (3) materia medica and pharmacy, (4) pharmacology. Candidates may present themselves in (a) and (b) separately.

Final M.B.—This examination deals with six subjects, which may be taken all together or divided into three parts: (1) General pathology, morbid anatomy, and bacteriology; (2) therapeutics; (3) forensic medicine, toxicology, and public health; (4) obstetrics and diseases of women; (5) surgery, systematic and clinical, including mental diseases and diseases of children.

M.D. and Ch.M.—Candidates for these degrees must have received the M.B. and Ch.B. at least a year previously. The M.D. candidate submits for approval a dissertation covering original work, the M.Ch. candidate undergoing an examination in all subjects of surgery, including ophthalmology. Other information concerning the diplomas of this university and its medical school will be found on page 332.

FELLOWSHIPS, SCHOLARSHIPS, AND EXHIBITIONS.

The university awards Fellowships annually to students of distinguished merit, as follows:

(1) Alexander Fellowship in Pathology and Bacteriology, value £100 and tenable for one year. (2) Ethel Boyce Fellowship in Gynaecology, value £100 and tenable for one year, open to fully qualified medical students of either sex. (3) John W. Garratt International Fellowship in Bacteriology, value £100 and tenable for one year. (4) Robert Gee Fellowship in Human Anatomy, value £100 and tenable for one year. (5) Holt Fellowships in Physiology and Pathology, two in number, value £100 each and tenable for one year. (6) Johnston Colonial Fellowship in Biochemistry, value £100 and tenable for one year. (7) Thelwall Thomas Fellowship in Surgical Pathology, value £100 and tenable for one year.

There are, in addition, scholarships and exhibitions open to medical students.

VICTORIA UNIVERSITY OF MANCHESTER.

This university grants the four ordinary degrees in medicine and surgery, M.B. and Ch.B. and M.D. and Ch.M.; a diploma and a degree (B.Sc.) in public health; a certificate in factory and in school hygiene; a diploma in psychological medicine; and a degree and diploma in dental surgery. Candidates for degrees must pass the special Matriculation Examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof; see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the five years' curriculum, one such year being subsequent to the passing of the First M.B. Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history; (4) English history; (5) two subjects at choice, one of which must be a language approved by the Joint Board, the other being elementary mechanics, or physics, chemistry, geography, natural history, or botany. It is held in July and September.

PROFESSIONAL EXAMINATIONS.

M.B., Ch.B.—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. At all examinations the subjects, or groups of subjects, prescribed can be taken separately or together, as the candidate pleases. The First M.B. is divided into Part 1, inorganic chemistry and physics;

Part 2, biology (including animal and vegetable morphology, physiology, and laboratory work); Part 3, elementary organic chemistry and biochemistry. The parts may be taken separately or together. At the Second M.B. the candidate is examined in anatomy and physiology; at the Third in pathology, hygiene, and pharmacology and therapeutics (including *materia medica* and practical pharmacy). The Final Examination includes medicine, systematic and clinical (separate papers being given on mental diseases), and diseases of children, surgery (systematic, clinical, and practical, with a separate paper on ophthalmology), obstetrics and gynaecology, and forensic medicine and toxicology.

M.D.—A candidate for this degree must be an M.B. of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (as well as practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject to be selected by the candidate.

Ch.M.—A candidate must have held, since becoming Ch.B., and for not less than six months, an appointment in a public institution affording opportunity for the study of practical surgery, and produce certificates of having attended certain courses of study. The examination comprises the general field of surgery, including ophthalmology and bacteriology.

FEES FOR EXAMINATIONS.

The following fees are payable: Matriculation, £2; on readmission, £1 10s. Each M.B. examination, £5; on re-admission, after failure, £2. M.D., including the conferring of the degree, £10. Ch.M., £5 each for the examination and degree. Application for further information should be addressed to the Dean of the Medical Faculty.

UNIVERSITY OF SHEFFIELD.

The degrees of this university (M.B., Ch.B., and M.D. and Ch.M.) and the diploma in public health are open to candidates of either sex. Candidates for a degree must have matriculated in the university or have passed such other examination as may be recognized for this purpose.

PROFESSIONAL EXAMINATIONS.

A candidate for the degrees of M.B., Ch.B. must produce certificates that he will have attained the age of 21 years by the day of graduation; that he has pursued the courses of study required by the university regulations during a period of not less than five years subsequently to the date of his matriculation, or exemption from matriculation, three of such years at least having been passed in the university, one at least being subsequent to the passing of the first examination. He or she has eventually to pass the following examinations in due order:

First Examination.—The subjects are chemistry, physics, and biology. The Intermediate examination in science—chemistry, physics, and zoology—will, on payment of the required additional fee, be accepted instead of this examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction, after matriculation, in (i) chemistry, inorganic and organic; (ii) physics; (iii) biology.

Second Examination.—The subjects are anatomy and physiology. The candidate must have completed the third winter session of professional study, must have passed the First Examination, and must have attended (1) lectures on anatomy, and dissections during five terms; (2) lectures on physiology during four terms; practical, experimental, and chemical physiology during four terms, and histology during one term.

Third Examination.—The subjects are pathology and pharmacology. Candidates must have completed the fourth year of medical study and completed the requisite courses in these subjects, including *post-mortem* clerkship for three months.

Final Examination.—The subjects are medicine (including forensic medicine, public health, mental diseases, and diseases of children), surgery, and obstetrics (including gynaecology). Candidates must satisfy the examiners in all subjects at the same examination. Candidates must have completed the fifth year of study.

M.D.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Ch.M.—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

UNIVERSITY OF WALES.

The Supplemental Charter and statutes of the University of Wales provide for a Faculty of Medicine and for the granting of the following degrees: Bachelor in Medicine (M.B.), Bachelor in Surgery (B.Ch.), Master in Surgery (M.Ch.), and Doctor in Medicine (M.D.).

A candidate for the M.B., B.Ch. cannot be admitted to examination until the completion of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed as a student in one of the constituent colleges of the university. He must also hold an Arts or Science degree of the University of Wales, or of some other university approved for this purpose. Some of the courses of study pursued for a B.Sc. or B.A. degree may be counted as part of the courses required for the degrees in the Medical Faculty.

The courses for the M.B., B.Ch. are divided into two sections, of which the first include the preliminary subjects—physics, chemistry, botany, zoology; and the ancillary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects must extend over at least one academic year, study of the ancillary subjects must extend over at least two academic years, and, excepting organic chemistry, cannot be commenced until all the preliminary courses have been completed; hence the first section of the course must occupy not less than three years. The second section includes courses in pathology, bacteriology, pharmacology, medicine, surgery, and obstetrics, and cannot be commenced, except in the case of pharmacology, until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in the earlier subjects are held at the end of each academic year, and in the subjects of the second section each July.

During the continuance of the war clinical service at a medical unit of the forces, or at an approved hospital, will be recognized as hospital practice, under certain conditions, for the purpose of the M.B. degree.

English Medical Corporations.

THERE are three medical corporations in England—the Royal College of Physicians, the Royal College of Surgeons, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the "Conjoint Board." Details concerning this body, its component colleges, and the third licensing body here follow.

THE CONJOINT BOARD.

This body deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who satisfy it for the licence and diploma of Membership respectively. The successful candidate is then entitled to admission to the *Medical Register* as an L.R.C.P.Lond., M.R.C.S.Eng. It performs the same task in connexion with diplomas in State medicine and tropical diseases jointly issued by the

two colleges in question. It obliges all candidates to pass one of a large number of examinations which it considers satisfactory tests of general education, and thereafter to pass five years in professional study at a recognized medical school, allowing, however, six months to be spent at any institution which may be recognized by the Board as giving efficient education in chemistry and physics. A list of such institutions, as also of the tests accepted in regard to general education, can be obtained from the Secretary of the Board at the Examination Hall, Queen Square, Bloomsbury, W.C.1.

PROFESSIONAL EXAMINATIONS.

There are three examinations for the Conjoint diploma, or L.R.C.P., M.R.C.S., which are commonly known as First Conjoint, Second Conjoint, and Final.

First Conjoint.—This examination is in four parts: (1) Chemistry, (2) physics, (3) elementary biology, (4) practical pharmacy.

A candidate must present himself for examination in Parts (1) and (2) together until he has reached the required standard to pass in both, or in one of these parts, but he will not be allowed to pass in one part unless he obtains at the same time half the number of marks required to pass in the other part. A candidate may take Parts (3) and (4) separately, or he may present himself for the whole examination at one time.

Before admission to either part the candidate must show that he has undergone certain courses of theoretical and practical instruction, but these courses need not be completed within one year, nor need they run concurrently, and they may be commenced or attended before the candidate passes the required preliminary examination in general education. A candidate referred in any part or parts will not be admitted to re-examination for three months. If referred in chemistry, physics, or biology, he must produce evidence of further instruction. Those who are already graduates in medicine, or who have passed an examination in the same subjects before a university board for a degree in medicine, may obtain exemption from re-examinations in those subjects at this examination.

Second Conjoint.—This examination deals with anatomy and physiology, and both subjects must be passed at the same time. A candidate must have attended at a recognized medical school lectures on anatomy, physiology, and a course of practical physiology and histology, and have dissected for twelve months during the ordinary sessions. The study of anatomy and physiology before passing in two of the first three parts of the first examination is not recognized. If rejected, a candidate, before being admitted to re-examination, must continue his studies at a recognized medical school for not less than three months.

Final Conjoint.—This examination consists of three parts: Part I, medicine, including medical anatomy, pathology, practical pharmacy,¹ therapeutics, forensic medicine, and public health; Part II, surgery, including pathology, surgical anatomy, and the use of surgical appliances; Part III, midwifery and gynaecology. The examination may be passed at one time or in each part separately. Evidence of attendance at courses of instruction in the subjects of the three parts must be produced, and also of having conducted twenty labours. A candidate will be admissible to Parts I, II, and III of the Third or Final Examination at the expiration of two years (twenty-four months) from the date of passing the Second Examination, and on production of the required certificates of study, provided that the examination is not completed before the expiration of five years (five winter and five summer sessions) from the date of passing the Preliminary Examination. A rejected candidate must produce evidence of further instruction during three months.

NOTE.—A person holding a Colonial, Indian, or foreign qualification which entitles him to practise in the country where such qualification has been obtained is, after a course of study and examination equivalent to those required by the Regulations of the two Royal Colleges, admissible to the Second and Third or Final Examinations without any interval. Members of an English, Scottish, or Irish university are under certain conditions eligible for admission to the Third or Final Examination two years after passing at their university the subjects included in the First and Second Examinations of the Board.

A member of an Indian, Colonial, or foreign university recognized for the purpose, who shall have passed examinations at

his university for the degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second Examinations of the Conjoint Board, will be eligible for admission to the Third or Final Examination two years after passing in the said subjects.

No special conditions relating to the war have been laid down, beyond allowing candidates to take midwifery before the completion of the fifth year of study. The committee of management, however, are willing to consider special cases where it has been difficult to fulfil certain details of the curriculum.

FEEES.

First examination, £10 10s. Re-examinations, Parts I and II, £3 3s.; Parts III and IV, each £2 2s. Second examination, £10 10s. Re-examination, £6 6s. Third examination, £21. Re-examination, Part I, medicine, £5 5s.; practical pharmacy, £2 2s. Part II, surgery, £5 5s. Part III, midwifery and diseases of women, £3 3s. Members of an English, Scottish, or Irish university, £5 5s. for examination and £36 15s. for the diplomas.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

This College has three grades—its Licentiates, its Members, and its Fellows. The Licence is now only issued through the Conjoint Board. The Membership is only granted to those who have passed the final examinations for the Licence; or those who are registered practitioners and graduates of a recognized university; in any case they must be persons over 25 years of age, who do not practise in partnership, dispense medicines, or engage in trade. Candidates are examined in pathology and the practice of physic, partly in writing and partly viva voce. Those under 40 are also examined in Latin, and either Greek, French, or German. The examination fee is £6 6s., the Membership fee being £42, or the difference between that sum and what the candidate has already paid if a Licentiate. The body of Fellows is maintained by election from among the Members.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

This College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose, who are required to attend for one year the surgical practice of a general hospital recognized by the College after obtaining their degrees. The College also issues a diploma in dentistry.

Fees.—At first examination: £5 5s. At second examination: £12 12s. Diploma fee: Members, £3 3s.; non-members, £13 13s.

SOCIETY OF APOTHECARIES OF LONDON.

This body confers a registrable diploma in medicine, surgery, and midwifery, now known as the L.M.S.S.A., on those successful at the following examinations:

Primary Examination.—This is divided into two parts, of which Part I includes elementary biology, chemistry, chemical physics, practical chemistry, pharmacy. Part II includes anatomy, physiology, and histology, and cannot be passed before the completion of twelve months' practical anatomy with demonstrations. The subjects cannot be taken separately, except in the event of the candidate having previously passed in one. Candidates will be excused any or all the subjects of the primary examination on producing evidence that they have passed equivalent examinations before an examining body recognized by the

¹ Candidates who have previously passed in practical pharmacy will not be re-examined in that subject at the Third Examination.

Society. Candidates referred in anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

Final Examination.—This is divided into two sections, the first of which is subdivided into three parts. Part I includes the principles and practice of surgery, surgical pathology, operative manipulation, surgical anatomy, instruments and appliances. Part II includes: (a) The principles and practice of medicine (including therapeutics, pharmacology, and prescriptions), pathology, and morbid histology; (b) forensic medicine, hygiene, theory and practice of vaccination and mental diseases. Part III includes midwifery, gynaecology, and diseases of newborn children, obstetric instruments and appliances. A candidate for any part of Section 1 must have passed not less than three winter sessions and two summer sessions at one or more of the medical schools recognized by the Society. Section 2 consists of clinical surgery and clinical medicine and medical anatomy, and a candidate before appearing at it must have completed five years of medical study.

FEES.

Primary examinations, £5 5s.; final, £15 15s. Further information may be obtained from the Secretary, Court of Examiners, Apothecaries' Hall, Blackfriars, E.C.4.

The Scottish Universities.

THERE are in Scotland four universities, each of them possessing a faculty of medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are on all fours with one another, so that an account can be given of all of them together.

The universities in question are those of Edinburgh, Glasgow, Aberdeen, and St. Andrews, and in point of standing and repute it is not easy to differentiate between them. What provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland; here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed an excellent repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides these degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, as also a diploma in psychiatry. As for public health, registrable degrees in this subject are granted both by the University of Edinburgh and that of Glasgow, while diplomas in public health may be obtained from the universities of St. Andrews and Aberdeen.

MATRICULATION.

There is a special matriculation examination for medical students, the subjects being English, Latin, elementary mathematics, and either Greek or French or German. Candidates are required to pass in all these subjects either at one or at not more than two examinations, but they can present themselves as often as they please. Many corresponding tests held by other bodies are accepted as the equivalent of this examination.

PROFESSIONAL EDUCATION.

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and in addition necessitate definite study for stated periods of diseases of children, of the larynx, ear and nose, of the skin, of ophthalmology, and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended regularly, but has duly performed the work of the class. Out of the necessary five years of medical study, not less than two must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the

beginning of October to the middle of March, and the other from the middle of April to the end of June.

PROFESSIONAL EXAMINATIONS.

The distinctive feature of the Scottish curriculum is that, though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may pass in physics and chemistry. At the end of the first summer session he can finish with botany and zoology, and with anatomy and physiology at the end of the second. Practical materia medica may be taken at any period of examination after the necessary course of instruction has been attended. Pathology and materia medica he will pass at the end of the third year, and soon, until the final examination in midwifery, surgery and medicine, and the corresponding clinical subjects at the end of the fifth year of study. At each examination the candidate may pass "with distinction," and a record is kept of the merit displayed, so that, when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with first or second class honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry; the second with anatomy and physiology; the third with materia medica and pathology; the fourth with medicine and surgery (clinical and systematic), midwifery, forensic medicine and public health, and clinical gynaecology. The first three examinations are held three times a year; the final twice a year.

Exemption from the first professional examination can be obtained by candidates who have passed a degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts, but is not successful in all of them, he is credited at the next examination with those subjects in which he has previously been approved.

THE HIGHER DEGREES.

It is open to those who are already M.B., Ch.B., to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the Naval or Military Medical Services, or have been at least two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and the thesis being on a surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

FEES.

It is estimated that the class, examination, and other fees for the M.B., Ch.B. come altogether to about £160, the separate examination fees included in this calculation being as follows:

	£	s.	d.
Preliminary Examination ...	0	10	6
First Professional ...	6	6	0
Second Professional ...	5	5	0
Third Professional ...	4	4	0
Final ...	7	7	0

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 1s. Candidates for the M.D. and Ch.M. pay £15 15s., and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 2d., which is published by Mr. Thin, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews information can be obtained either from the Secretary of

the University, or alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that, in connexion with all the Scottish universities there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

Owing to the war, special final examinations may be held for such students as have fulfilled the requirements of the curriculum of the General Medical Council.

The Scottish Corporations.

THERE are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

THE CONJOINT BOARD IN SCOTLAND.

THIS body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L.R.C.P. Edin., L.R.O.S. Edin., and L.R.F.P.S. Glasg. The Board requires all candidates to comply with the regulations of the General Medical Council. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council.

PROFESSIONAL CURRICULUM.

Subsequent to registration as a medical student, the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not exact that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held six times every year—four times in Edinburgh and twice in Glasgow; and it is open to candidates to present themselves for examination at either place. The first examination deals with physics, chemistry, and elementary biology; the second with anatomy and physiology, including histology; the third with pathology and materia medica, including pharmacy; and the final with (1) medicine, including therapeutics, medical anatomy, and clinical medicine; (2) surgery, including surgical anatomy, clinical surgery, and diseases and injuries of the eyes; (3) midwifery and diseases of women and of newborn children; and, if it has not been passed previously, (4) medical jurisprudence and hygiene. Candidates may also be examined on diseases of children, diseases of the ear and throat, insanity, vaccination, etc.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the final examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the third examination and of his study of these subjects; but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously.

A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

Part or entire exemption from the three first examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own; but all candidates for the conjoint licence must sit for the final examination, and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

FEES.

It is estimated that the total cost of lectures and fees for the conjoint licence is about £152. The separate examination fees are as follows: First, Second, and Third Professional, £5 each; Final, £15. On re-entry for any of the first three examinations £3, and on re-entry for the Final, £5. If the re-entry is only in one or two subjects, the fees are smaller.

Information concerning this Board should be sought either from Mr. D. L. Eadie, 50, George Square, Edinburgh, or from Mr. Walter Hurst, Faculty Hall, 242, St. Vincent Street, Glasgow.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THIS College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, but for the Fellowship women are not eligible. As an original qualification the Licence is only granted after fulfilment of the regulations of the Conjoint Board, but as an additional qualification it can be obtained by those already possessed of a registrable qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body. The fee is £15 15s., of which £10 10s. is returned to unsuccessful candidates. On due cause being shown, a special examination may be granted, the fee being £20, of which £10 is returned to a candidate if he is not approved.

Candidates for the Fellowship must be not less than 25 years of age, and have been in practice subsequent to registration for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or an approved diploma obtained as the result of an examination which includes surgery as well as medicine. Candidates are examined in surgery, including clinical and operative surgery, surgical anatomy, and one other subject which they may choose from among the following: Ophthalmology, laryngology including aural and nasal surgery, dental surgery, advanced midwifery with obstetric surgery, gynaecology, surgical pathology and operative surgery, and advanced anatomy. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice, his application for admission being supported by two Fellows of the College, one of whom must be resident in Edinburgh, or, in default, by testimonials obtained specially for the purpose.

No changes in the curriculum or examinations have been made in consequence of the war.

Licentiates of the College pay £35, and others £45. For further information application should be made to the Clerk of the College, Mr. D. L. Eadie, 50, George Square, Edinburgh.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THIS College has three grades—Licentiate, Membership, and Fellowship; to the two latter women are not admissible. The regulations applying to candidates for the Licentiate have already been generally indicated. If desirous of receiving it apart from those of the other two corporations, they must be holders of a surgical qualification recognized by the College, and must pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board, and conditioned in the same way, and also an examination in materia medica. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take

place monthly on the first Wednesday, except in September and October. A candidate for the Membership must be either a Licentiate of a Royal College of Physicians or a graduate in medicine of a British or Irish university, and in either case not less than 24 years of age. He is examined in medicine and therapeutics, and in one further subject at his choice. This may be either (a) one of the departments of medicine specially professed; (b) psychology; (c) general pathology and morbid anatomy; (d) medical jurisprudence; (e) public health; (f) midwifery; (g) gynaecology; (h) diseases of children; or (i) tropical medicine. Licentiates of the College pay £21, others £36 15s. The examination is held quarterly, and application for admission to it must be made a month previous to its date. For the Fellowship, the candidate must have been a member of the College for at least three years, and, if accepted, pays fees amounting altogether to a little less than £65. Any further details required can be obtained on application to the Secretary of the College.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

This body possesses two classes—Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s., and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. Special regulations are in force for medical practitioners serving in the present war. The Faculty can also elect four Fellows annually without previously submitting them to examination, provided they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age. Further information can be obtained from Mr. A. Duncan, B.A., LL.D., Faculty Hall, St. Vincent Street, Glasgow.

The Irish Universities.

THERE are three universities in Ireland, and each of them has a medical faculty. These are the University of Dublin, usually known as Trinity College, Dublin, the Queen's University of Belfast, and the National University of Ireland. The two former teach students, examine them, and grant or withhold degrees accordingly; while the third is by way of being an academic body only, inasmuch as its practical work is divided up among three constituent colleges, situated, one at Cork, another at Galway, and the third in Dublin. The regulations of all these universities in respect of medical degrees are given in the following sections; while specific information as to the arrangements for the education of medical students made at each of them will be found in the section relating to Irish Medical Schools.

UNIVERSITY OF DUBLIN: TRINITY COLLEGE.

This university grants two degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and diplomas in the same subjects and in public health. It also confers two degrees in dentistry. The degrees are granted to those who, besides having passed the Professional Examination, have graduated in arts.

PROFESSIONAL EXAMINATIONS.

A candidate for the Final Examination for the M.B., B.Ch. and B.A.O. degrees must be a matriculated student of at least five years' standing; and though he need not have taken his degree in arts before admission to the Professional Examination, he cannot take his medical degrees until he has been admitted B.A. At least three years of the five years' medical curriculum must be pursued at the School of Physic of the university. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admis-

sion to any of these examinations students must be duly signed up as regards study in the subjects involved.

Preliminary Scientific.—This covers (a) chemistry, (b) physics, (c) botany and zoology; the three divisions may be taken together or at different times.

Intermediate Medical.—This is divided into two parts: (a) Anatomy, physiology, organic chemistry, and histology; (b) applied anatomy and applied physiology. The two parts may be taken separately or together.

Final Examination.—Part I: Hygiene and medical jurisprudence, pathology, materia medica and therapeutics. Part II: (a) Midwifery, gynaecology (clinical, paper, and viva voce); (b) medicine, clinical medicine, and mental diseases; (c) surgery in all branches, including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, and the final cannot be taken before the end of the fifth year.

M.D.—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B.A. three years previously. He must read a thesis before the Regius Professor of Physic.

M.Ch.—The candidate must be a B.Ch. of not less than three years' standing, and have been engaged in practice for two years. Graduates of ten years' standing may be given a special examination.

M.A.O.—The candidate must have passed the qualifying examination in medicine, surgery, and midwifery. The examination is specially directed to obstetrics and practical gynaecology.

For the university diplomas mentioned above the candidate must have completed two years in arts and five in medical studies. The examination and courses required are the same as for the degrees.

Further information regarding courses of instruction, etc., may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

QUEEN'S UNIVERSITY, BELFAST.

The degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), Master of Obstetrics (M.A.O.). The university also confers a diploma in public health. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine.

PROFESSIONAL EXAMINATIONS.

The examinations for the M.B., B.Ch., B.A.O. are four in number. The first deals with: (1) Inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology, and may be taken at the end of the second year of the student's career. The Third Examination includes: (1) Pathology, (2) materia medica, pharmacology and therapeutics, (3) medical jurisprudence, and (4) hygiene. To be valid a certificate in regard to the study of the subjects of this examination must show that the work has been done after the First Examination has been passed.

The Final Examination includes: (1) Medicine, (2) surgery, (3) midwifery, (4) ophthalmology and otology. The student may pass in all subjects at once at the end of his fifth year, or he may divide the examination into two parts—namely, (1) systematic, (2) clinical, practical, and oral. The first part may be taken at the end of the fourth year, but for the second part the candidate may not present himself until the end of his fifth year. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination.

THE HIGHER DEGREES.

Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing,

unless they hold also a degree of the university in arts or science. In that case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (a) after a formal examination, or (b) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) a written paper on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and viva voce examination, and (4) a written paper and clinical or practical and viva voce examination on a subject chosen from the following list: (1) Human anatomy, including embryology, (2) physiology, (3) pathology, (4) pharmacology and therapeutics, (5) sanitary science and public health, (6) forensic medicine and toxicology, (7) mental diseases. The regulations for the degrees of M.Ch. and M.A.O. are of the same general nature.

NATIONAL UNIVERSITY OF IRELAND.

The National University of Ireland carries on most of its educational work through three constituent colleges—one in Dublin, one in Cork, and one in Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation or recognition as a student of the Medical Faculty obtained in some other fashion. The candidates at each constituent college are examined thereat by the university, and a common standard of education is secured by all courses of instruction and the regulations concerning them having to be approved by the Senate after considering report thereon from the Board of Studies of the University. In addition to the ordinary degrees in medicine and surgery, the university grants those of Bachelor and Master of Obstetrics, Bachelor and Doctor of Science in Public Health, and Bachelor and Master in Dental Surgery, as well as diplomas in Public Health, in Mental Diseases, and in Tropical Medicine.

PROFESSIONAL EXAMINATIONS.

There are four examinations. The first, which should be passed at the end of the first year, includes Part A (chemistry and physics) and Part B (botany and zoology), which parts candidates may take separately or together. At the end of the second year they should pass in anatomy and physiology; and at the end of the third year in pathology, *materia medica* and therapeutics, hygiene and public health, forensic medicine, and toxicology. The final examination is divided into three parts, each of which may be taken separately—namely, (a) Medicine, including mental diseases; (b) surgery, including ophthalmology and otology; (c) midwifery and gynaecology.

The higher degrees are obtainable either by examination or on presentation of an approved work, but in each case not less than three years must have elapsed since the candidate acquired the corresponding degree of Bachelor. Further information as to the constituent colleges will be found in the section relating to Irish Medical Schools.

The Irish Corporations.

THERE are three licensing bodies other than the Medical Faculties of the Universities, and, just as in London, there are two Royal Colleges of Physicians and Surgeons and an Apothecaries' Hall. The similarity is still more complete, for in Ireland also the two colleges have formed an examining Conjoint Board, as in London, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall gives its Licence separately.

THE CONJOINT BOARD IN IRELAND.

This body requires of candidates the passage either of its own preliminary examination in the subjects of general education, or proof that the candidate has passed one of the tests accepted by the General Medical Council.

PROFESSIONAL EXAMINATIONS.

There are four professional examinations, the first of which cannot be passed earlier than the end of the first winter session, nor the fourth before the conclusion of full five years of medical study, and before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The first and second examinations deal respectively with (a) chemistry and physics, and (b) biology; and (a) anatomy, and (b) physiology and histology. All parts of these examinations, as also of the following one, which deals with (a) pathology, (b) *materia medica*, pharmacy, and therapeutics, (c) public health and forensic medicine, may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least four years have passed in medical studies other than those for the first examination, and five years, at least, since the beginning of the curriculum. The divisions are (a) medicine, including fevers, mental diseases, and diseases of children; (b) surgery, including ophthalmic and operative surgery; (c) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination. Candidates are recommended to present themselves in all the subjects of the Final Examination at one time, but a candidate at or after the end of the fourth year may present himself in any one of the divisions (a), (b), or (c), provided he has completed his curriculum as far as concerns the division in which he presents himself.

Fees.—Preliminary Examination, £2 2s.; re-examination, £1 1s. First Professional Examination, £15 15s.; Second, £10 10s.; Third, £9 9s.; Final, £6 6s.; re-examination fee is £2 2s. for each division.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, 123, St. Stephen's Green, Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

Those whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College, and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to all university graduates in medicine and Licentiates in medicine of Royal Colleges of Physicians, and deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members of the College, irrespective of sex.

Fees.—For the Licence in Medicine, 15 guineas; for the Licence in Midwifery, 5 guineas; or 16 guineas for both if they are taken within an interval of a month. Special examinations cost in each case 5 guineas extra. For the Membership, 20 guineas to a Licentiate of the College; 35 guineas to others; a special examination costing 10 guineas extra. The Fellowship £35, in addition to stamp duty, £25. Information as to special examinations and other points can be obtained from the Registrar, the Royal College of Physicians, Kildare Street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the College of Physicians, but it is given separately to holders of a registrable qualification in medicine, provided that the College is satisfied that adequate courses of study have been pursued, and provided its own provisional examination

is passed. This examination is held on its behalf by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

The Fellowship.—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology; and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly *viva voce*; while the final examination includes the performance of operations. All subjects of either examination must be passed at one time, and to neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle the holder to admission to the Register; if, however, the candidate is a person whose name is on the Colonial or foreign medical Register, at the discretion of the Council. Candidates for the Final Examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

Fees.—Candidates for the Licence pay 5 guineas for examination, which sum, if they pass, is counted as part of the fee payable on admission to the Licence, this being 25 guineas. Candidates for the Fellowship pay 5 guineas for each examination, the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiate, and 40 guineas in the case of others.

APOTHECARIES' HALL OF IRELAND.

A DIPLOMA is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Two periods of dissection, each not less than six months, must be included, and twenty-seven months of hospital attendance, or its equivalent. Three professional examinations have to be passed; they are held three times a year. The Primary Examination deals with biology, physics, and chemistry, practical and theoretical; the Intermediate Examination is in practical anatomy and physiology, and histology and materia medica. A candidate who has passed tests in any of the subjects of these examinations before another licensing body is exempt from further examination in such subjects. The Intermediate Examination, Part II, consists of pathology, medical jurisprudence, and hygiene. The Final Examination deals with medicine, surgery, midwifery, and pharmacy. The Hall's own examination in all these subjects must be passed. Women candidates are eligible.

Fees.—Primary Examination, £4 4s.; Intermediate Examination, £8 8s.; Final Examination, £12 12s.; Final alone, when the others have been passed elsewhere, £15. Application for other information should be made to the Registrar, 40, Mary Street, Dublin.

MEDICAL SCHOOLS AND COLLEGES.

LONDON.

APART from post-graduate and other special schools, the medical schools of London number as many as fourteen, including in the count two institutions which provide education only in the preliminary and intermediate subjects, under the title of "university centres."

Little guidance can be given in these columns as to choice of one school rather than another, for such choice must depend largely on personal factors. In a general way, however, it may be said that while to the student of to-day it may, perhaps, be almost a matter of indifference to what school he belongs, there is often in after-life a certain advantage in having been an alumnus of one of the more celebrated schools. On the other hand, at the smaller schools more opportunities, perhaps, present

themselves to the average man for obtaining student appointments, and especially the coveted posts of house-physician and house-surgeon.

Information as to the fees at the different schools, and the scholarships, prizes, and junior appointments which they offer will be found in the following pages, and should be carefully studied by those who have no personal reason for preferring one school to others. The courses which they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, as has been said, special facilities are offered to men who have commenced their professional education at the older universities, Oxford and Cambridge. Apart from these facts, the only point to which attention can usefully be directed is that on personal inquiry and investigation reason may perhaps be found for regarding the teaching accommodation and general arrangements for students at some schools as superior to those at others.

CHARING CROSS HOSPITAL.

THIS school, with its hospital, is situated in the very centre of London, and is accessible from all parts by train, tram, tube, or 'bus, a convenience to students which at once solves the difficulty of where to reside. Indeed, it is quite possible to live twenty miles away in the heart of the country and still attend the teaching in its entirety. Its courses of instruction are specially designed to meet the requirements of the University of London, the Conjoint Board, and the final studies of other universities. The hospital contains 300 beds. Over 3,000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for mental diseases, midwifery, diseases of women, of children, of the skin, eye, ear, throat, nose, and teeth, for tuberculosis, orthopaedic cases, x-ray work, and for electrical examination and treatment.

Appointments.—Demonstratorships and assistant demonstratorships are open to students of the school. Medical, surgical, and obstetric registrars to the hospital are appointed annually. Six house-physicians, six house-surgeons, and two resident obstetric officers are appointed each year.

Primary and Intermediate Studies.—By an agreement with the University of London the school sends its primary and intermediate students to receive their lectures and practical work at King's College, which is situated within four minutes' walk. This arrangement has proved most successful. It enables students to obtain the best university education in their earlier studies from a large professorial and teaching staff, whilst allowing them to take advantage of their own school for social and collegiate purposes.

Final Studies.—The final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for the qualifying examinations. Departments are also available for the other final subjects of bacteriology, clinical pathology, materia medica, toxicology, public health, operative surgery, and for research work.

Public Health Laboratories.—An exceptionally fine series of laboratories in the school has been taken over by the University of London King's College, to which a full professorial and teaching staff has been transferred. The course of instruction for the Diploma in Public Health is given in these laboratories.

The Museum contains over 4,000 specimens, including a notable collection of over 800 gynaecological specimens—"The Outhbert Lockyer Collection."

Students' Club.—The social comfort and convenience of students are met by library, reading, and smoking rooms, refreshment room, etc. The club, which is under the control of a committee of students, provides various athletic recreations and includes the Medical Society.

Women Students.—Women students are accepted by the school and hospital upon the same terms and conditions as men, and after qualification are eligible for resident hospital appointments. A separate common room and a

female attendant are provided, but beyond this no further distinction is made. This system of co-education, under which men and women are placed on terms of complete equality throughout the whole of the curriculum, has been found to work successfully and to their mutual advantage.

Fees.—These are arranged upon the simplest and most comprehensive plan. An entrance fee of 10 guineas and 8 guineas is payable by full-course and final-course students respectively, and an annual fee of 26 guineas covers all other expenditure, with the exception of 7 guineas for vaccination, dispensing, and fever hospital attendance, which must be taken outside the hospital. Membership of the Students' Club is included in these fees.

Post-Graduate Work.—Special facilities are offered for post-graduates desiring to do research work in the school or hospital or to attend the regular courses of instruction. The fees are low and inclusive.

Further information may be obtained on application to the Dean, W. J. Fenton, M.D., F.R.C.P., Medical School, Charing Cross Hospital, London, W.C.2.

GUY'S.

The hospital contains 643 beds in constant occupation. Thirty-three beds are set apart for diseases of the eye and 40 for the most urgent and interesting medical cases, which form the subjects of the weekly clinical lectures. There is a special ward of 32 beds for the reception of cases of diseases of women and for cases of difficult labour. Beds are also allotted to the throat and ear departments, the orthopaedic department, the department for the treatment of diseases of the genito-urinary system, and the children's department; there are as well some special beds for the treatment of syphilis.

The medical college fronts the east gate of the hospital, providing accommodation for 60 resident students. This contains a dining-hall, reading rooms, a library of general literature, and a gymnasium for the use of the residents and of the members of the Clubs Union. The athletic ground at Honor Oak Park is reached from the hospital in twenty minutes. The Gordon Museum of Pathology, the Wills Library, the newly built Departments of Chemistry, Physics, Pathology, and Pharmacology, and the school buildings in general, afford unrivalled opportunities for a liberal education and for research. Special classes are held for the First and Second Examinations for Medical Degrees of the University of London and for the first F.R.C.S.Eng. Special teaching is provided to meet the requirements of the universities of London, Oxford, and Cambridge in general pathology and pharmacology.

Appointments.—All appointments are given to students without extra payment, and according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, eight house-physicians, twenty assistant house-surgeons, eight house-surgeons, two ophthalmic house-surgeons, and nine resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, and ophthalmic house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant, dresser, or clerk in the special departments of ophthalmology, laryngology, gynaecology, diseases of children, diseases of the nervous system, dermatology, otology, electricity, anaesthetics, and dentistry. More than 150 additional appointments have been added to the list of those annually open to students of the hospital, the majority of them being in the special departments.

Scholarships, Prizes, etc.—The following entrance scholarships are awarded annually in the month of September: A. Junior Scholarships in Arts, Classics, Mathematics, and Modern Languages, and Science, of the value of £120, £100, and £50, open to candidates under 21 years of age. B. Senior or University Scholarships of the value of £75 and £35, open to candidates under 25 years of age, who have completed their study of Anatomy and Physiology. Subjects, any two of the following: Anatomy, Physiology, Pharmacology, General Pathology, Organic Chemistry. Junior prizes for general proficiency, £20, £15, £10; Hilton prize for Dissection, £5; Michael Harris prize for Anatomy, £10; Sands-Cox Scholarship for Physiology, £15 for three years; Wooldridge Memorial prize for Physiology, £10; Beaneys prize for Pathology, £34; Treasurer's gold medal in Medicine, Treasurer's

gold medal in Surgery, and the Golding-Bird gold medal and scholarship for Bacteriology (£20) are awarded annually after competitive examination. The Gull Studentship in Pathology, and the Beaneys Scholarship in Materia Medica, of the annual value of £150 and £31 10s. respectively, are awarded without examination to enable research to be carried on in these subjects. An Arthur Durham Travelling Scholarship of £100 is awarded triennially. The Douglas Research Studentship in Pathology, value £300 per annum, is awarded without examination.

Various modifications have been rendered necessary by the war. In agreement with the practice of the universities, an allowance will be made for military service performed by candidates.

Fees.—An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School.

KING'S COLLEGE HOSPITAL.

The medical school carried on in connexion with this institution, at Denmark Hill, deals with the advanced or final subjects of the medical curriculum. The arrangements for education in these subjects are complete. The new and up-to-date hospital contains over 600 beds, many of which are given up to the 4th London General Hospital (T.F.). There are special departments for diseases of women and children, nervous diseases, ophthalmology, otology, laryngology, dermatology, dental surgery, etc.; pathological and vaccine departments are also included.

Appointments.—Sixteen resident medical and surgical officers are appointed yearly, as well as dressers and clerks in the wards, out-patient departments, *post-mortem* room, and special departments. Each of the special departments has several clinical assistants. There are three registrars and three tutors, all of whom receive salaries. The Clubs and Societies Union combines athletics, music, and other societies connected with the school, and provides also a common room.

Fees.—The composition fee is 70 guineas if paid in one sum, or 72 guineas in two instalments (one of 40 guineas at entrance, and the other of 32 guineas at the commencement of the second year). Entrance fee ten guineas.

The prospectus of the school can be obtained on application to the Dean, H. Willoughby Lyle, M.D., B.S.Lond., F.R.C.S., or to the Secretary, S. C. Ranner, M.A.Cantab., King's College Hospital, Denmark Hill, S.E.5.

THE LONDON.

This hospital, with its medical college and dental school, are situated in the Mile End Road, E.1. The hospital contains 922 beds, and, during 1916, 17,637 patients passed through the wards and 130,831 patients received treatment in the out-patient departments; these numbers include 7,814 accident cases. The number of major operations which were performed amounted to 6,160.

From the beginning of the war to the close of 1916 3,947 military patients were admitted, while the naval patients (who were first admitted at the end of September, 1915) totalled 384.

The building of the wards for the treatment of syphilis has now been completed. During 1916, 620 patients were admitted for treatment.

All the departments are modern and adapted for the teaching of all subjects in the curriculum. A residential hostel on hospital ground is provided for the convenience of students who wish to live near the wards and casualty departments. The athletic ground is at Highams Park, and is open to all members of the Clubs Union.

Appointments.—The salaried appointments open to students are those of medical registrar (3), surgical registrar (3), obstetric registrar, registrar in the ear, nose, and throat department (2), medical, surgical, and obstetric tutors; senior dressers to out-patients; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopaedic, and electrical departments. There are 2 resident accoucheurs, 6 resident house-physicians, and 9 resident house-surgeons, 7 receiving-room officers, 2 emergency officers, 1 assistant director of Pathological Institute, and 3 pathological assistants, also paid and unpaid clinical assistants in the various special departments. In addition there are numerous assistant-

ships, clerkships, and dresserships in the various departments.

Scholarships and Prizes.—The following is a list of scholarships and prizes:—At Entrance: Price Scholarship in Science, £100; in Anatomy and Physiology, £52 10s.; Entrance Scholarship in Science, £50; Epsom Scholarship, "Free Medical Education"; Buxton Scholarship in Arts, £31 10s. After Entrance: Anatomy and Physiology Prize, £25; Letheby Prizes, £25; Prizes in Clinical Medicine, Surgery, and Obstetrics, £20 each; Duckworth Nelson Prize, £10; Hutchinson Prize, £40; Sutton Prize, £20; Sir Andrew Clark Prize, £25; Anderson Prizes, £30; Dressers' Prizes, £40; Practical Anatomy Prizes, £10; Wynne Baxter Prize, £5 5s.; Arnold Thompson Prize, £5; Harold Fink Prize in Dental Surgery, £5 5s.; Prize in Dental Microscopy, £5. The London Hospital Medical College and the Eliza Ann Alston Medical Research Funds amount to over £23,000.

Fees.—Entrance fee, 10, 15, or 30 guineas, according to examinations passed; annual fee 30 guineas. Full information may be obtained from the Dean at the London Hospital Medical College, Mile End, E.1.

THE MIDDLESEX.

The school and hospital are in Mortimer Street, W., close to Oxford Circus, Goodge Street, and Great Portland Street stations. There is a residential college for a limited number of students overlooking the hospital garden, a gymnasium within the precincts of the hospital, and an athletic ground within easy distance at Park Royal. The hospital contains 449 beds, including a wing containing 92 beds for patients suffering from cancer, and special cancer investigation laboratories, which offer unrivalled opportunities for the study of this disease, both in its clinical and pathological aspects. In connexion with the investigation laboratories there are several valuable scholarships awarded.

There are special wards for maternity and gynaecological cases, and for diseases of children and of the skin and eye.

The Bland-Sutton Institute of Pathology is under the charge of a director. The institute includes a pathological and anatomical museum, a lecture theatre, large pathological and public health laboratories, and smaller rooms for original investigation. Bacteriological, chemical, and microscopical examinations of material from the wards, operating theatres, and out-patient departments are carried out in the laboratories. Senior students are eligible for clerkships in the laboratories of the institute, and every facility is given for original investigation.

In the electro-therapeutical department special attention is given to the treatment of lupus and cancer by the *x* ray, and opportunities are afforded to students wishing to become acquainted with the use of the apparatus employed in this method of treatment. An electro-cardiographic department has also been established.

Appointments.—Twenty-two resident appointments are open annually for competition among students of the hospital. The officers reside and board in the residential college free of expense. Two casualty medical and two casualty surgical officers, and two resident officers to the special departments, are appointed annually. Eight house-surgeons are appointed every year at intervals of two months, after examination; six house-physicians are also appointed annually at similar intervals. An obstetric and gynaecological house-surgeon is appointed every six months. In the out-patient departments the appointments are: clerk and dresser to the physicians and surgeons to out-patients; clerk in the departments for diseases of the skin and nervous diseases; dresser to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, and to the dental surgeon. Extern midwifery clerks and *post-mortem* clerks are also appointed. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Students must have held an out-patient clerkship and dressership before being eligible to hold in-patient clerkships or dresserships. Non-resident qualified clinical assistants are appointed in the Medical, Surgical, Skin, Neurological, Ophthalmic, Throat and Ear, Odontological, Children's, and Electro-therapeutical Out-patient departments.

Scholarships.—Three Entrance Scholarships, value £100, £50, and £25 respectively, are open to students commencing their medical studies in April or October, 1915. An annual Entrance

Scholarship, of the value of £50, is open to students of the universities of the United Kingdom who have completed the curriculum for, or passed the examinations in, anatomy and physiology. The examination for these scholarships will take place on September 17th, 18th, and 19th. Application for admission must be made on or before September 8th. Students joining the school in the previous April are eligible. The Freer Lucas Scholarship is annually awarded on the nomination of the head master to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, value £50, awarded annually to students from New Zealand. In addition to the Entrance Scholarships, there are numerous other valuable scholarships, prizes, and exhibitions open to students of the hospital, including the Brodrip Scholarships, value £60 and £40; Lyell Gold Medal and Scholarship, value £55 5s.; Freeman Scholarship, value £30; John Murray Gold Medal and Scholarship, value £25; Hetley Clinical Prize, value £25; Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas.*

Fees.—The composition fee for students taking the University of London degree is 145 guineas, or by five equal annual instalments of £32 11s. For those who have passed the first examination for medical degrees the fee is 120 guineas, or by four equal annual instalments of £34 2s. 6d. Students taking the Conjoint Board diplomas pay 135 guineas, or by five equal annual instalments of £30 9s. Students who have passed the First Professional Examination pay 115 guineas, or by four equal annual instalments of £32 16s. 3d. For members of universities and others who have completed their anatomical and physiological studies the fee is 70 guineas, or three equal annual instalments of £26 5s.

Further information may be obtained on application to the Dean.

ST. BARTHOLOMEW'S.

This institution fills one side of Smithfield and Giltspur Street, sharing with the Post Office buildings a large island of ground separated practically from all other buildings; it is on the edge of the City, and easily reached from all parts of London. The hospital contains 750 beds. Extensive new buildings, opened in July, 1907, occupy part of the ground acquired from the old Bluecoat School, and these materially enhance the attractions of the hospital as a place of medical study. The medical school buildings, including the library and the chemical, physical, biological, and physiological laboratories, and anatomical department have now at their side a very large building, which includes club rooms for the Students' Union, a writing room, luncheon and dining halls, new quarters for the resident staff, and an out-patient department and accommodation for special departments of such large size as to be unsurpassed by any hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to a new and extensive *post-mortem* room, large and well-equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. Within the precincts of the hospital also there is a residential college for a large number of students. The Students' Union owns, moreover, grounds of some 10 acres in extent for recreative purposes at Winchmore Hill, which is easily accessible from the hospital.

Special classes are held for students preparing for the Preliminary Scientific and other examinations for the M.B., M.D. of the Universities of London, Oxford, and Cambridge, and for the higher surgical degrees at the same universities, including the M.Ch.Oxon., M.C.Cantab., M.S.Lond., and F.R.C.S.Eng. Special laboratory instruction for the D.P.H. of Cambridge, Oxford, Durham, and London is also given.

Appointments.—Clinical clerks to the physicians and to the physician-accoucheur, and dressers to the surgeons and in the casualty department, are chosen from the students; clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special departments (Ophthalmic, Orthopaedic, Gynaecological, Laryngological, Aural, Dermatological, Electrical, and Dental), and in the *post-mortem* room. Chief assistants and clinical assistants are selected from qualified men appointed yearly to help in the general medical, surgical,

* Certain of these scholarships have been modified for the period of the war, particulars of which can be obtained on application.

and in the special departments. Ten house-physicians and ten house-surgeons are appointed annually. During their first six months of office they act as "Junior" house-physicians and house-surgeons, and receive a salary of £25 a year. During their second six months they become "Senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two resident assistant anaesthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year.

Scholarships.—Five entrance scholarships are annually awarded after an examination held in September. The subjects of examination and conditions of eligibility for these scholarships are: (1) Two scholarships, value £75 each, in not fewer than two and not more than three of the following subjects—Chemistry, Physics, Botany, Zoology, Physiology, and Anatomy, limited to students under 25 years of age who have not entered on the medical or surgical practice of any London medical school. One scholarship, value £150, in not fewer than three of the following subjects—Chemistry, Physics, Botany, Zoology, and Physiology, limited to students under 21 years of age who have not entered on the medical or surgical practice of any London medical school. (3) The entrance scholarship in Arts, of the value of £100, will be given in Latin and mathematics, with one other language—Greek, French, or German. (4) The Jeffreys Exhibition in Mathematics, Latin, and one other language—Greek, French, or German—and of the value of £50. The value of the scholarships and prizes is over £1,000 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical School, St. Bartholomew's Hospital, E.C.1.

ST. GEORGE'S.

THIS school is at Hyde Park Corner, and is carried on in connexion with St. George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital founded by Atkinson Morley at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centres of London University established at King's College and University College. As a temporary measure for the duration of the war a small and strictly limited number of women students have been admitted to the clinical course in the school. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of university and all other examinations receive careful attention.

The St. George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well-filled library of medical and scientific books. A register of accredited apartments, and a list of medical men and others willing to receive St. George's men as boarders, may be seen on application to the Dean.

Appointments.—Dresserships to the surgeons and clinical clerkships to the physicians are open without fee to all students of the hospital. There is a large number of resident appointments, which may be held for six, twelve, or eighteen months, and are open without fee to every perpetual student of the hospital, and are made strictly in accordance with the merits of the candidates. Besides this, after the student has held a house appointment, the following are, among others, open to him: Medical registrarship at £200 per annum; surgical registrarship at £200 per annum; assistant curatorship of the museum at £100 per annum; obstetric assistantship, resident, at £50 per annum; the post of resident anaesthetist at £100 per annum; the post of senior anaesthetist at £50 per annum; the posts (2) of junior anaesthetists, each at £30 per annum.

Scholarships.—Two university entrance scholarships in anatomy and physiology (70 guineas and £50) are awarded at the commencement of each winter session. The William Brown Exhibition of the value of £112 per annum (tenable for

two years) is awarded by examination to a perpetual pupil of the hospital every second year. The William Brown Exhibition of £42 (tenable for three years) is awarded by examination to a perpetual pupil of the hospital every third year. Other prizes to the value of £200 are awarded annually to the students of the hospital.

Fees.—First year (preliminary science or first conjoint), £26 5s., or £21, according to course. Second and third years, £63 in two equal instalments. For the course of clinical study, in the fourth and subsequent years, entrance fee, £10 10s.; annual composition fee, £31 10s. No entrance fee is payable by St. George's students who have studied at King's and University Colleges.

Further information may be obtained from the Dean of the Medical School.

ST. MARY'S.

THIS school and its hospital are situated in Praed Street, in the neighbourhood of the residential districts of Paddington, Bayswater, and North Kensington, and are thus especially convenient to students who wish to reside in the immediate vicinity. A register of approved lodgings is kept in the office of the Medical School.

The athletic ground at Park Royal, Acton, is easily accessible from the Medical School. It is seven acres in area, and provides ample accommodation for the various athletic clubs; the pavilion is large and well equipped.

The hospital contains 305 beds, of which 31 are devoted to treatment by therapeutic inoculation.

The Medical School provides complete courses in the preliminary and intermediate subjects of the curriculum which are recognized by the University of London as approved courses for internal students. Students may join in October, January, or April.

The departments of biology, chemistry, anatomy, physiology, and pathology are under the direction of full-time lecturers, and special courses are provided twice yearly for the Primary F.R.C.S. In addition, special tuition is provided for the Intermediate and Final Examinations of the universities of Oxford, Cambridge, and London, and for the Final F.R.C.S.

All clinical appointments in the hospital are free to students of the school, and the resident medical officers are chosen by competitive examination. Six house-physicians, six house-surgeons, four obstetric officers, and two resident medical officers to the inoculation wards are appointed each year, and receive board and residence in the hospital. A large number of salaried appointments are open annually to qualified students, including those of medical registrar, surgical registrar, casualty physician, casualty house-surgeon, resident assistant anaesthetist, assistant curator, together with several demonstratorships. In the inoculation department there are nine assistantships, the salaries of which amount to £1,600 per annum.

Scholarships.—There are Entrance Scholarships in Natural Science; one of £100, one of £50, one of £25, and two University Scholarships of £52 10s. awarded annually by competitive examination in September.

Fees.—The composition fee for students is £140 if paid in one sum, or £145 if paid in four instalments. University students who have completed their examinations in anatomy and physiology are admitted on payment of a composition fee of 65 guineas (£68 5s.) paid in one sum, or 70 guineas (£73 10s.) if paid in two annual instalments. A system of annual fees is also in operation for students who prefer it. Separate courses of lectures, laboratory work, or hospital practice may be taken.

The School Calendar and full information can be obtained from the Secretary, St. Mary's Hospital Medical School, Paddington, W.

ST. THOMAS'S.

THIS school and hospital are situated in Lambeth, the joint buildings on the Thames facing the Houses of Parliament, and forming one of the well-known architectural features of London.

The school buildings, which are separated from the hospital by a quadrangle, comprise lecture theatres, laboratories, and class-rooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading room and a complete museum are open to all students from 9 a.m. to 5 p.m., on Saturdays to 2 p.m. The Students'

Club premises contain a dining room and smoking and reading room supplied with daily and illustrated weekly papers, and a gymnasium. Good meals are obtainable at a moderate tariff. The Terrace affords facilities for exercise and recreation. A cloak-room with lockers, and a lavatory with bath-rooms, are in the main school building. Students are thus able to spend the whole day at the school. The sports ground of more than nine acres in extent is at Chiswick. It can be reached in forty minutes from the hospital; it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital proper contains 664 beds, and temporary huts erected in the quadrangles afford accommodation for 350 additional patients. In addition to the ordinary provisions of a great hospital there are connected with the out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that large numbers of students are enabled to follow closely the practice and teaching of the out-patient staff. There is a full complement of special departments, and connected with the hospital a special tuberculosis department gives opportunity for instruction of students. There is a clinical theatre, centrally situated, so as to facilitate the illustration of lectures by patients from the wards and out-patient room; it is arranged also for lantern demonstrations. The maternity ward, containing 20 beds, gives students full facilities for maternity training, under supervision, within the precincts of the hospital. This obviates any necessity for supplementary instruction elsewhere, and fully prepares the student for the extern maternity practice of the hospital district. The revised regulations of the examining bodies can thus be fully complied with.

Appointments.—All hospital appointments are open to students without charge. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £150 each, with board and lodging. Two hospital registrars, at an annual salary of £50 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. An obstetric tutor and registrar is appointed each year at an annual salary of £50. Eight resident casualty officers and anaesthetists are appointed every six months. Four house-physicians, four house-surgeons, two obstetric house-physicians, two ophthalmic house-surgeons, and eight clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. Two research assistants (bacteriological and chemical) are paid £200 per annum each. Clinical clerkships and dresserships to the in-patient and out-patient departments are available to the number of 400 each year.

Scholarships.—There are five entrance scholarships: Two in Arts, giving one year's free tuition; one of £150 and one of £60, in Chemistry, Physics, and Biology, for students who have not received instruction in Anatomy or Physiology; one of £50 in any two of the following subjects: Anatomy, Physiology, or Chemistry, for students who have completed their examinations in Anatomy and Physiology, for a medical degree in any of the universities of the United Kingdom, and have not entered as students in any London medical school. Valuable scholarships, prizes, and medals are open for competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in Pharmacology, and the Louis Jenner Research Scholarship of the annual value of £50 for Pathological research.

Fees.—The entrance fee for second year's students is 20 guineas; for third year's students 10 guineas. The annual composition fee is 30 guineas. For Preliminary Science students the fee is 15 guineas. The fees cover all tutorial classes given by the school teachers, and there are no extra charges made for materials required in practical courses. Special courses of instruction are given for various examinations, and a register of lodgings is kept at the school. A list of medical practitioners, clergymen, and others who receive students is also available. Further information may be obtained from the Secretary of the School, St. Thomas's Hospital, Albert Embankment, S.E.1.

UNIVERSITY COLLEGE HOSPITAL.

The school, which forms part of the Corporation of University College Hospital, is in immediate proximity to the hospital in University Street and opposite University College. It comprises departments of medicine and clinical medicine, surgery and clinical surgery, midwifery

and gynaecology, pathology including morbid anatomy, clinical pathology and bacteriology, cardiography, forensic medicine, mental physiology and mental diseases, dental surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear, and throat, and for instruction in anaesthetics, electro-therapeutics, and skiagraphy. The Hospital and School have acquired the National Dental Hospital and College as their Dental Departments, thus providing every facility for the study of dental subjects.

The school thus provides the final course of study for the degrees of the universities of London, Oxford, Cambridge, and Durham, and for the diplomas of the Royal Colleges of Physicians and Surgeons in Medicine and Dental Surgery, and the Licence of the Society of Apothecaries. Special bacteriological classes are also held in preparation for the various diplomas of public health. Each department is also equipped for more advanced work, and provides facilities for research.

A student may enter the medical school at the commencement of his career, in which case he will pursue his preliminary and intermediate studies at the University of London, University College, and his final studies in the school. He may also enter the school for the final studies after having completed his preliminary and intermediate studies at any recognized university or school.

Scholarships.—The following scholarships and prizes are open to competition: Two Entrance Exhibitions of 80 guineas each, awarded after a competitive examination in anatomy and physiology; the Graham Scholarship in pathology of a sum not exceeding £200 per annum; the Atkinson Morley Scholarship of £45 a year for three years, awarded after examination in the theory and practice of surgery; the Atchison Scholarship of £55 a year for two years for general proficiency in medical studies; the Magrath Clinical Scholarship, value about £100; the Filliter Exhibition in pathology of £30; the Percival Alleyn Prize for the advancement of surgery by research, value about £60; the Graham Gold Medal for research work; four Fellowes Medals in clinical medicine; Liston Medals in clinical surgery; the Bruce Medal in pathology and surgery; two Tuke Medals in pathology, and the Erichsen Prize for practical surgery.

Appointments.—All the appointments at the hospital are reserved for students of the school, the dresserships and clerkships being open, of course, to those who have still to qualify. The qualified appointments, in addition to a number of posts as house-physicians and house-surgeons and obstetric assistants, include the appointments of resident medical officer, surgical registrars, obstetric registrar, casualty medical officers, casualty surgical officers, assistant in ear, nose, and throat departments, assistant in ophthalmic department, registrar in anaesthetic department, and deputy anaesthetists.

Fees.—The fee for the full course of final studies at the school is 80 guineas if paid in one sum, or 82 guineas if paid in two instalments.

Particulars of general and special courses can be obtained on application to the Dean of the Medical School.

WESTMINSTER.

This school, with its hospital, situated in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College. The rest of the work is done in the school buildings near the hospital, which contains upwards of 200 beds, and affords most ample facilities for instruction in all branches of medicine and surgery.

Appointments.—A medical and surgical registrar are appointed annually, each with a salary of £50. Two house-physicians, three house-surgeons, one assistant house-physician, one assistant house-surgeon, and a resident obstetric assistant are appointed after examination, and are provided with rooms and commons, except the assistant house-physician and the assistant house-surgeon, who are provided with commons only. The assistant house-physician after three months' service becomes house-physician for a further period of six months, and the assistant house-surgeon, after two months' service, becomes house-surgeon for a further period of six months. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge or special departments, are appointed from among qualified students. Every student must perform the duties of out-patient dresser for four months, and afterwards

hold the office of in-patient dresser for four months. He is also required to serve two terms of four months each as medical clinical clerk to in-patient physician and one term as gynaecological clinical clerk. Two pathological clerks are appointed every four months to assist in the post-mortem room. No student is eligible as an in-patient dresser or clinical clerk until he has passed the Second Examination of the Conjoint Board, or an equivalent examination. Clerks and dressers in the special departments of hospital practice are periodically appointed. So far as vacancies permit, students of other hospitals are admitted to in-patients' dresserships or clerkships.

Scholarships.—The following scholarships are offered for competition during the year 1917-18: In the summer session two natural science scholarships, £60 and £30, and one in Arts, £60. In the winter session two scholarships in anatomy and physiology, £50 each. In the spring two scholarships in anatomy and physiology, £50 each.

Fees.—The annual composition fee is 26 guineas, and an entrance fee of 10 guineas is payable by every student, including scholars. These fees include subscriptions for membership of the Clubs Union.

Further information can be obtained on application to the Dean at the Westminster Hospital Medical School, Caxton Street, Westminster, S.W.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

THIS school is carried on at 8, Hunter Street, Brunswick Square, W.C.1, in connexion with the Royal Free Hospital. An agreement has also been made under which students of the school receive clinical instruction at St. Mary's Hospital, Paddington. It is, like all the other London schools which have so far been mentioned, one of the constituent schools of the Medical Faculty of London University. The school buildings have recently been enlarged. The laboratories are extensive and well lighted, and are fully equipped for the examination courses of the University of London. Research laboratories are attached to all departments.

A large, well-equipped library, common-room, union-room, and refectory are provided for the use of students. There is also some residence accommodation for students in the school buildings.

The Royal Free Hospital, Gray's Inn Road, W.C.1, has 184 beds, all of which are available for clinical instruction. A new block contains the Maternity Department, with a lying-in ward of 8 beds, new and enlarged students' quarters, a new Out-patients' Department, with special operating theatre, and departments for massage, electrical and x-ray work, dentistry, and casualty. There are also separate departments for gynaecology and obstetrics and diseases of the eye, ear, and skin. Instruction is given in anaesthetics, bacteriology, etc., in addition to the ordinary clinical lectures and demonstrations and tutorial classes. Students attending at St. Mary's Hospital (305 beds) are admitted to the full clinical course and educational facilities of the hospital. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board, and receive special instruction in lunacy at Bethlem Hospital; they are also admitted to the practice of a number of special hospitals.

The work of the school includes preparation for the M.B., B.S. Lond., and the diplomas of the Royal Colleges of England (including the Primary Fellowship examination), also for the medical school and general hospital course for dental students.

Appointments.—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical and medical registrars, pathologists, anaesthetists, medical electrician, skiagrapher, curator of museum, and clinical assistants and demonstrators in various subjects.

Scholarships.—The Isabel Thorne Entrance Scholarship value £30, the St. Dunstan's Medical Exhibition value £60 a year for three years, which may be extended to five years, and the Mabel Sharman-Crawford Scholarship, value £20 a year for four years, are offered for competition in each year. The Mrs. George M. Smith Scholarship, of the value of £50 a year for three years, which may be extended to five years, and the Sarah Holborn Scholarship, of the value of £20 a year for three years, which may be extended to five years, are awarded in alternate years. The Bostock Scholarship, value £60 a year for two or four years, is awarded by the Reid Trustees on the result of an examination held in May by the University of London. The holder of the

scholarship must enter the London School of Medicine for Women. The Agnes Guthrie Bursary for Dental Students, value £60, is awarded each year. The Ellen Walker Bursary of £25 for two years is awarded each year to a student beginning her fourth year of study. The John Byron Bursary of £20 a year for two years, the Helen Frideaux Prize of £40, the Mabel Webb Research Scholarship of £30 for two years, the Fanny Butler Scholarship of £14 10s. a year for four years, together with many other scholarships and prizes, are offered on sundry conditions. The Dr. Edith Pechey-Phipson Post-Graduate Scholarship of £40 is awarded annually. Various missionary societies also offer scholarships on certain conditions, and assist ladies who wish to go to India and other countries as medical missionaries.

Fees.—Courses for the University of London, diplomas of Royal Colleges of England, and other qualifications: First medical examination, £28; course for second and third, £141; course after the second medical examination, £91. These sums include library and laboratory fees.

The Students' Union exists to promote corporate action of the students on matters of common interest, and to promote and maintain athletic and other clubs. All students are required to become members of the Union.

Further information can be obtained from the Warden and Secretary.

KING'S COLLEGE.

SINCE the incorporation of King's College in the University of London, the instruction given to medical students is carried out there in the classes of the Faculty of Science (Medical Division), and deals only with the subjects of the preliminary and intermediate parts of the curriculum. King's College Hospital (see p. 325) is now a separate institution, and the studies for the final examinations only are carried out there.

A special class for the Matriculation Examination is also held.

There is a large athletic ground at Wormwood Scrubbs, managed by the Students' Union Society.

Scholarships.—The entrance scholarships are: 1. Three Warneford Scholarships, each £25 for four years; subjects—mathematics, classics, divinity. 2. One Sambrooke Exhibition of £25 for two years, open; subjects of examination—mathematics, elementary physics, inorganic chemistry, botany, and biology. The holders of the preceding awards must proceed to King's College Hospital. 3. *Rabbeith Scholarship, value £20, in July, for the best student of the first year. 4. *Second year's scholarship, value £20, for the best student of the second year.

Fees.—Information as to fees can be obtained from the Dean of the Medical Division of the Faculty of Science at the College (Professor W. D. Halliburton, M.D., F.R.C.P., LL.D., F.R.S.).

Women Students.—King's College is now open to women students for the Preliminary and Intermediate portions of the medical curriculum. Application for admission should be made to the Dean.

Information as to scholarships and subjects of examinations can be obtained from the Secretary of the College.

UNIVERSITY COLLEGE.

THIS institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology; and also the intermediate medical sciences—namely, anatomy, physiology, and pharmacology. These courses in intermediate medical sciences will, as from October, 1917, be open to women students on the same terms as to men. The preliminary medical science courses have for many years been open to women students. The Department of Hygiene and Public Health prepares for the diplomas in public health of the Royal Colleges and of the various universities. Research work is undertaken in all the above-named departments, as well as in pathological chemistry, the work of which is entirely post-graduate. It undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, accordingly as whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the

* Suspended during the war.

whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. The general arrangements for the benefit of students include membership of the Union Society, with its gymnasium and athletic ground. There is also a collegiate residence for about forty men students at Ealing.

Scholarships.—The scholarships and exhibitions obtainable include the Bucknill Scholarship, value 135 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School), and two entrance exhibitions on the same subject, each of the value of 55 guineas.

Fees.—The fees for the courses covering the work of the First Examination for medical degrees of the University of London, and in both parts of the Second Examination, amount to 84 guineas. The fees for the courses covering the corresponding examinations held by the Conjoint Board in England come together to 79 guineas. These fees may be divided into payments for the different courses which it may be desired to take out, but do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Provost of University College.

COOKE'S SCHOOL OF ANATOMY.

THIS school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half a dozen students in the course of the year; these have special advantages, both as regards anatomy and physiology. The operations of surgery are performed on the dead body. Special classes in surgery are constantly held.

The school, which is open all the year round, possesses a good collection of anatomical models, physiological and chemical apparatus, and gentlemen preparing for the higher examinations (F.R.C.S. Eng., M.B. Cambridge, Oxford, London, etc.) receive special instruction in the more difficult subjects. Other information may be obtained from Mr. Knight, 46, Mecklenburgh Square, W.C. 1.

THE PROVINCES.

THERE are in England and Wales, not counting London, ten medical schools, each, with one exception, supplying instruction in the full medical curriculum. Accounts of them here follow. In several cases there is appended information concerning other hospitals than those directly connected with the school in question; such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

OXFORD AND CAMBRIDGE.

BOTH at Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently equipped, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them, but this is not commonly done. The local hospitals are comparatively small, so the authorities encourage the students, as soon as they have completed the earlier examinations, to join some London school, and thus spend the time of their preparation for the final examination in a city where the opportunities for gaining clinical knowledge are greater and more varied.

BIRMINGHAM.

THE school in this city is carried on by the Medical Faculty of the University of Birmingham, its students having an adequate number of good laboratories, classrooms, and other necessities devoted to their use by the university. The clinical work is done at the General and Queen's Hospitals, which are amalgamated for this purpose. Together they have upwards of 500 beds for medical, surgical, and special cases, and with an array of special departments of all kinds, including one for lying-in women. Clinical instruction is given in the wards and out-patient and special departments daily, and

formal clinical lectures delivered weekly throughout the winter and summer sessions. Special tutorial classes are also held alike for the degrees of Birmingham and some other universities and for the diplomas of corporations.

Appointments.—The large number of appointments open to past or other students includes the following:—At the General Hospital: one resident medical officer, salary £100 a year; one resident surgical officer, salary £100 a year; one resident pathologist, salary £50 a year; two non-resident casualty assistant physicians, salary £50 a year; three non-resident surgical casualty officers, salary £50 a year; two non-resident anaesthetists, salary £50 a year; four house-surgeons, office tenable for nine months, £50 a year; one house-surgeon to the gynaecological and one to the ophthalmic and aural departments, each tenable for six months, £50 a year; three house-physicians, post tenable for six months, £50 a year; one resident medical officer at the Jaffray Branch Hospital, salary £150 a year; one resident assistant at the Jaffray Branch Hospital, tenable for three months. At the Queen's Hospital: three house-physicians and three house-surgeons (posts vacant in January and April); one obstetric and ophthalmic house-surgeon (posts vacant in April and October). These appointments are tenable for six months. Salaries at the rate of £90 per annum, with board, lodging, and washing. One resident dresser, tenable for three months; candidates must previously have attended their third-year lectures, etc., and need not be qualified. Honorarium, £13 13s. on completion of duties. At the Maternity Hospital: one house-surgeon, salary £50 a year. At the City Workhouse and Workhouse Infirmary: five resident medical officers. At the Birmingham General and Branch Dispensaries: twelve resident surgeons. At the Birmingham Lunatic Asylums: five assistant medical officers. At the City Fever Hospitals: three assistant medical officers. At the Children's Hospital: one resident surgical officer, one resident medical officer. At the Birmingham and Midland Eye Hospital: four resident surgeons. At the Orthopaedic and Spinal Hospital: two clinical assistants (non-resident). At the Ear and Throat Hospital: one house-surgeon, £70 a year; four clinical assistants (non-resident). There are also four non-resident Poor Law appointments in the gift of the Board of Guardians.

Scholarships.—There are numerous money and other awards for students of sufficient merit, among them being the following: The Walter Myers Travelling Studentship of £150; the Sands-Cox Scholarship of £42 (an entrance scholarship in the Faculty of Medicine, awarded on either matriculation or First M.B. marks); four Queen's Scholarships of £10 10s. each, awarded annually at the second, third, fourth, and final university examinations respectively; one or more Sydenham Scholarships, allotted on entrance to students who are the sons of deceased medical men. The Ingleby Scholarship of £10 for proficiency in midwifery and diseases of women. There is also an entrance scholarship of £37 10s. for students proceeding to a degree in dental surgery. University Clinical Board Prizes are awarded annually as follows: Senior Medical Prize, Gold Medal; Senior Surgical Prize, Gold Medal; Midwifery Prize, Gold Medal; Junior Medical Prize, Silver Medal; Junior Surgical Prize, Silver Medal.

Fees.—The composition fee for university classes is £85. This covers all the work required for the degrees of Birmingham and some other universities, and for the ordinary qualifications of licensing corporations, but not the additional courses required for the Fellowship of the Royal College of Surgeons of England, the diploma and degrees of the university in State medicine, and some other special work. The total cost for the five years' curriculum, including hospital and examination fees, is estimated at £158 2s. 6d. Other information should be sought from the Dean of the Medical Faculty.

BRISTOL.

THE school is carried on by the Faculty of Medicine of the university, and provides full instruction for all its degrees and diplomas. The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them about 600 beds and extensive out-patient departments, special clinics for diseases of women and children, and those of the eye, throat, and ear, in addition to arrangements for dental work and large outdoor maternity departments. At each of these institutions there are well-arranged pathological departments, comprising large pathological museums, post-mortem rooms, and laboratories for morbid anatomy.

There are also laboratories for work in clinical pathology, bacteriology, and cytology, in which special instruction is given in these subjects. Departments are provided and well equipped for x-ray work both in diagnosis and treatment, the various forms of electrical treatment, including high-frequency currents, electric baths, Finsen light treatment, and massage.

The students of the school have also the advantage of attending the practice of the Royal Hospital for Sick Children and Women, containing 108 beds, and that of the Bristol Eye Hospital, with 40 beds. Excellent facilities are thus afforded to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work. Each student has the opportunity of personally studying a large number of cases and acquiring practical skill in diagnosis and treatment. All classes are open to women.

Appointments.—(1) Undergraduate: Clinical clerkships, dresserships, also ophthalmic, obstetric, and pathological clerkships are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate—At the Bristol Royal Infirmary: Four house-surgeons, £100 each per annum; four house-physicians, £100; resident obstetric and ophthalmic house-surgeon, £100; throat, nose, and ear house-surgeon, £100; dental house-surgeon, £100. All these appointments are made for twelve months. From the resident officers a senior resident officer is appointed at an additional salary of £30. At the Bristol General Hospital: Senior house-surgeon, £200 per annum; casualty house-surgeon, £100 per annum, if another resident appointment has been previously held; two house-physicians, £80 per annum; house-surgeon, £80 per annum, obstetric house-surgeon, £80 per annum; dental house-surgeon, £200 per annum. All these appointments are for six months, except those of senior house-surgeon and dental house-surgeon, which are for two years.

Scholarships.—The following are among the scholarships and other awards open to students of the school: Two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 9 guineas, for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth-year students for general proficiency; the Augustin Prichard Prize, value 7 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for general proficiency; the Crosby Leonard Prize, value 7 guineas, for proficiency in surgery; the Suple Surgical Prize, a gold medal and 7 guineas; the Suple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10s., for general proficiency.

Fees.—The fee for all the courses required for the medical curriculum, including hospital practice, is 135 guineas if paid in one sum. It amounts to 150 guineas if paid by annual instalments.

CARDIFF.

The school in this city is carried on by the University College of South Wales and Monmouthshire, and devotes itself at present principally to training students during the first three or four years of the medical curriculum, all classes being open to women students. The courses of instruction given are recognized by all licensing bodies in Great Britain, and after passing the tests corresponding to the first three years of the curriculum, the student can complete his course, for whatever degree he is aiming at, in London or elsewhere. Besides this, there is an arrangement with the Management Committee of the infirmary by which students at the school can take advantage of the opportunities for acquiring experience afforded in the wards of this large, well-ordered hospital. Hence many students, especially from Wales and Monmouthshire, find it convenient to avail themselves of the advantages of being able to pursue the earlier part of their medical curriculum near home. They can also obtain instruction in vaccination and in the administration of anaesthetics and with a little additional work can qualify for the B.Sc. degree of the University of Wales. This degree includes the subjects which comprise the first three years of a medical student's curriculum, and it (or the B.A.) is a compulsory degree for those students who propose to sit for the M.B., Ch.B. of the University of Wales. There is also a department of public health, in which all the work for diplomas in State medicine, whether for the University of Wales or other Examining Boards, can be done. A

Chair of Pathology and Bacteriology has been established. It is hoped that before long a complete Welsh National School of Medicine will be established at Cardiff, owing to the munificent offer of Sir William James Thomas to erect and present to the college a school of preventive medicine and medical school buildings, in addition to the Physiological Laboratory he has already provided.

Post-graduate vacation courses are carried on in association with the Cardiff Infirmary.

Scholarships.—There is a considerable number of scholarships connected with the college, and open to students of the School of Medicine, information as to which can be obtained on application.

Fees.—The composition fee for the three years' courses required for students proceeding to the M.B.Lond. is £63; that for the two years' courses for students proceeding to a diploma of the licensing corporations being £41 10s. The composition fee for D.P.H. classes is £30. Further information may be obtained on application to the Dean of the Faculty of Medicine.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

THIS, the Medical School of the Faculty of Medicine of the University of Durham, is in the neighbouring city, Newcastle-on-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees which the latter grants, and also those of the other examining bodies. The students do their work in the preliminary sciences at Armstrong College, also part of the university, and their clinical work in the new Royal Victoria Infirmary, an institution with over 400 beds and special accommodation for the benefit of students. In a new wing of the school itself there are the departments of bacteriology and physiology. There are also in this wing a gymnasium and a set of rooms for the use of the Students' Union.

Appointments.—Assistant demonstrators of anatomy and prosectors for the professor of anatomy, assistant physiologists, pathological assistants, assistants to the dental surgeon, and assistants in the eye department, throat and ear department, and department for skin diseases, are elected annually. Four times in the year clinical clerks and dressers are appointed for three months.

Scholarships.—A University of Durham Scholarship, value £100, for proficiency in arts, open annually at the beginning of the winter session to intending students. The Pear Scholarship, value £150, for proficiency in arts (when vacant). The Dickinson Memorial Scholarship, interest of £400, with a gold medal, for medicine, surgery, midwifery, and pathology, open to perpetual students in their fifth year. The Tulloch Scholarship, interest of £400 annually, for elementary anatomy, biology, chemistry, and physics, for students at the end of their first year. The Charlton Memorial Scholarship, interest of £700 annually, open to full students entered for the class of medicine, at the end of their fourth or fifth winter. The Gibb Scholarship, interest of £500 annually, for pathology, at the end of summer session. Gibson Prize, interest of £240, for midwifery. Outtersen Wood Prize, interest of £250, for psychological medicine. The Goyder Memorial Scholarship, proceeds of £325; subjects: Clinical medicine and clinical surgery. Luke Armstrong Memorial Scholarship, proceeds of £580, for best essay in some subject in comparative pathology. The Stephen Scott Scholarship in Surgery, interest on £1,000 annually. The Heath Scholarship in Surgery, interest on £4,000, awarded every other year. First award in 1896.

Fees.—The composition fee for lectures at the college is 80 guineas. Composition fee for hospital practice 35 guineas, plus £2 2s. yearly for three years payable to the Committee of the Royal Victoria Infirmary. Other information should be sought from the Secretary of the School at Newcastle.

Other Hospitals.—The Hospital for Sick Children and the Infirmary for Diseases of the Eye throw open their various departments to students.

LEEDS.

THE School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The buildings were opened in 1894, and contain excellent dissecting rooms, several well arranged laboratories for physiology, pathology, and bacteriology, three lecture theatres, and several similar class-rooms.

In addition, there are a library and reading room and two museums, one being devoted to pathology and the other to anatomy. The comfort of the students is secured by common rooms and a refectory in which they can take meals. It is estimated by the authorities that the approximate cost of medical education to a student in this university is £202, *plus*, of course, the expenses of living during the five years covered by the curriculum. The General Infirmary has 532 beds, and includes gynaecological and ophthalmic wards and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge, attached to the infirmary, has 88 beds. The West Riding Lunatic Asylum at Wakefield is also open for the study of mental diseases. Students can, in addition, attend the practice of the Leeds Public Dispensary (where the practical instruction in dental subjects is also given), the City Fever Hospitals (100 beds), the Hospital for Women and Children, and the Leeds Maternity Hospital.

Appointments.—One senior anaesthetist, £50; seven assistants, £25 each; medical and surgical tutor, at £125 each per annum; one resident medical and one surgical officer, each at £150 per annum; one casualty officer, at £125 per annum; one resident ophthalmic officer, at £100 per annum; one resident aural officer, at £100 per annum; one resident obstetric officer, at £50 (attached to the gynaecological ward and an extensive external maternity department); one ophthalmic house-surgeon, at £50 per annum; three house-physicians, each holding office for six months, and four house-surgeons, holding office for six months. Surgical dressers are appointed every six months; physicians' clerks, ophthalmic and aural dressers, gynaecological ward clerks, gynaecological out-patient clerks, maternity clerks, assistant physicians' clerk, dermatological clerk, and assistant surgeons' dressers, dressers in the casualty room, *post-mortem* clerks, and laboratory assistants every three months. A clinical pathologist (£300 per annum), together with an assistant clinical pathologist (£150), has charge of the pathological laboratory. A resident medical officer (honorary, £30) is also appointed every six months for the Ida Semi-convalescent Hospital. Appointments are also open to students at the Leeds Public Dispensary (one senior and four junior resident medical officers, with salaries commencing at £80), at the Hospital for Women (two house-surgeons, at £50 per annum, and two anaesthetists, £20), and at the West Riding Asylums.

Scholarships.—The university awards annually a scholarship in the form of a free admission to the lectures and classes given in the university, which are covered by the composition fee. The infirmary also awards a scholarship on the results of the first examination, of the value of 40 guineas, in the form of a free admission to the clinical teaching of the infirmary.

Fees.—The fee for a complete course for the First M.B. is £27 11s.; the composition fee for the course for the second and third examinations is £73 2s. 6d. (for students who have passed the second examination, £48 16s. 6d.), and for the clinical work at the infirmary, £42.

Further information can be obtained from the Dean and Clinical Subdean, School of Medicine, Leeds.

LIVERPOOL.

The Medical School of this city is part of the university, and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories, as well as with ordinary spacious and well-equipped class rooms and laboratories for the instruction of students proceeding to medical degrees and diplomas in special and ordinary subjects. All the laboratories and other rooms are situated close to one another and intercommunicate, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospitals, of which an account is given below, have amalgamated to form the clinical school of the university.

Appointments.—The nature of the appointments open to past and other students at this school will be gathered from the account which follows of the hospitals forming its clinical department.

Scholarships.—The awards made each year to successful students total over £1,000. They include the following: Two Holt Fellowships, one in Pathology, the other in Physiology; a Robert Gee Fellowship in Anatomy; an Alexander Fellowship for Research in Pathology and Bacteriology; a John W. Garrett International Fellowship in Bacteriology; a Johnston

Colonial Fellowship in Biochemistry; an Ethel Boyce Fellowship in Gynaecology; and a Thelwall Thomas Fellowship in Surgical Pathology, all of the value of £100; a University Scholarship of £25 awarded on the results of the Second M.B. Examinations; a Scholarship in Mechanical Dentistry of £20; two Lyon Jones Scholarships, of the annual value of £21 each for two years, one for the junior and the other for senior students; the Derby Exhibition of £15; the Clinical School Exhibition of £15; the Owen T. Williams Prize; the Torr Gold Medal in Anatomy; the George Holt Medal in Physiology; the Kanthack Medal in Pathology; the Robert Gee Prize of £5 5s. in Children's Diseases; two Robert Gee Entrance Scholarships, each of the value of £25 per annum for two years; Orthodontia Prizes, Senior £3 3s., Junior £1 1s.; one Thomas H. Bickerton Prize in Anatomy; Dental Operating Prizes, Senior £4 4s., Junior £2 2s.; Ash's Prize in Dental Surgery, value £2 2s.; and other Entrance Scholarships.

Fees.—Information as to the fees paid for the courses of instruction provided by the schools should be sought from the Dean of the Medical Faculty.

The Clinical School.

As many as nine hospitals have combined to form the clinical school of the university, these being: The Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, the Stanley Hospital, the Infirmary for Children, the Hospital for Women, the Eye and Ear Infirmary, St. Paul's Eye Hospital, and St. George's Hospital for Diseases of the Skin. Between them they provide about 1,140 beds.

MANCHESTER.

The staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and their later studies, being of an elaborate nature. The clinical work of the undergraduates is done chiefly in connexion with the Royal Infirmary, an institution which itself contains about 592 beds, and has associated with it a large convalescent home and the Royal Lunatic Asylum at Cheadle. Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St. Mary's Hospitals.

Appointments.—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition: A surgical registrar, at £75 per annum; a pathological registrar, at £100 per annum; a medical registrar, at £75 per annum; a surgical tutor, at £30 per annum; a director of the clinical laboratory, at £250 per annum; and one assistant director at £75; three assistant medical officers and three assistant surgical officers, each at £35 per annum; one assistant surgical officer, aural department, at £35 per annum; five anaesthetists, at £50 per annum each; one medical officer for skiagraphy and electricity, £100 per annum; one medical officer for home patients, one year, £150 per annum; one resident medical officer, one year, £150 per annum; ditto, at Cheadle, one year, £150 per annum; one resident surgical officer, one year, £150 per annum; two resident medical officers for Central Branch, £100 per annum; one accident room house-surgeon, six months, £100 per annum; one assistant medical officer at the Convalescent Hospital at Cheadle, appointed every six months, at a salary of £80 per annum; eight senior and eight junior house-surgeons and ten house-physicians, appointed during the year for a term of six months. Resident officers are appointed to the Gynaecological, the Eye, and the Ear and Throat departments every six months. Four or more clinical clerks are attached to each physician and assistant physician, and four or more dressers to each surgeon and assistant surgeon, to the Gynaecological surgeon and assistant Gynaecological surgeon, to the Ophthalmic surgeon, and to the surgeon for the Ear and Throat department, and four or more clerks to the Pathologist, two clerks to the Director of the Clinical Laboratory, and a number of clerks, not exceeding six, are appointed to assist the medical officer for home patients. Accident-room dressers are appointed every three months, three senior dressers and twelve or more junior dressers.

Entrance and other Scholarships.—The following are among the scholarships obtainable by students of the school: Robert and Seaton Scholarships in Arts (in alternate years), £40 per annum, tenable for two years. Two Dalton (entrance) Scholarships in Mathematics, tenable for two years, value £40, one being awarded annually, except in such years as a Cartwright Scholarship is awarded. Cartwright Scholarship, £34

per annum, tenable for three years. Three Hulme Scholarships, tenable for three years, of £35, one being awarded annually for proficiency in subjects of general education. Two James Gaskill Scholarships of £35, tenable for two years, one being awarded annually for proficiency in the branches of Mechanics and Chemistry. A Dora Muir Scholarship, £30 per annum, tenable for three years, and open to the competition of women students only. This is awarded triennially. Sir J. P. Kay-Shuttleworth Scholarship, £30 per annum, tenable for three years, open to the competition of scholars from Sedburgh School, Giggleswick School, and Burnley Grammar School. Subjects: Mathematics, Chemistry, and Mechanics. Dreschfeld Memorial Scholarship, value £30, tenable for one year and awarded triennially on the result of the Entrance Examination. A Theodores Modern Languages Exhibition, £20, awarded annually. Two Dauntsey Medical Scholarships, value £45 and £35, tenable for one year, for candidates who have not commenced the second year of study leading to a medical qualification. Subjects: Zoology, Botany, and Chemistry. Two Entrance Scholarships in Medicine, value £100, awarded annually for proficiency in Arts or Science respectively. Two Research Fellowships in Public Health of £50 each, awarded annually. Tom Jones Exhibition in Anatomy, £25, offered annually. Robert Platt Physiological Exhibitions: Two, about £15 each, offered annually. A Robert Platt Physiological Scholarship of £50, tenable for two years. A Robert Platt Zoological and Botanical Scholarship, £50. A Leech Fellowship of £100 for original research after graduation. A Graduate Scholarship in Medicine, value £25, tenable for one year, awarded annually for proficiency shown at Final M.B. Examination. A Dumville Surgical Prize, value £15, awarded annually at graduation. The Tom Jones Memorial Surgical Scholarship, value £100, tenable for one year, awarded usually triennially. The Turner Medical Scholarship, value £20, awarded annually for proficiency in certain subjects of the Final M.B., Ch.B. Examination. The John Henry Agnew Scholarship of £30, awarded annually for proficiency in the Diseases of Children. The Bradley Memorial Scholarship in Clinical Surgery of £20. The Ashby Memorial Scholarship, tenable for one year (£100), for research in the Diseases of Children; offered triennially. Sidney Renshaw Exhibition in Physiology: One, offered annually. The details and regulations of the Dickinson Scholarships—(1) for Anatomy, (2) for Pathology, (3) Research Scholarship in Surgery, and (4) Travelling Scholarship in Medicine—will be announced later. The Sam Gamble Scholarships—the trustees are prepared to award four scholarships of not less than £40 per annum, tenable for not more than four years, to women students who have passed the First M.B. Examination. The conditions under which these scholarships are awarded can be obtained from the Registrar.

Fees.—The composition fee for the university course in medicine is 70 guineas, payable in three instalments of 30, 20, and 20 guineas, but this sum does not include the fee to cover the work required for the First M.B. Examination. This is £25, payable in one sum. A prospectus and further information about the school and scholarships may be obtained on application to the Registrar.

Clinical Work.—The Royal Eye Hospital, the Manchester Northern Hospital for Women and Children, the well-known Hospitals for Children at Pendlebury, and St. Mary's Hospital for Diseases of Women and Children all make arrangements for the instruction of students.

SHEFFIELD.

In this city the Medical School is one of the departments of the University, being conducted and controlled by its Medical Faculty, and occupying practically the entire north wing of the quadrangle of the university buildings overlooking Weston Park. The laboratories and lecture rooms connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangements and scientific equipment, on the most modern and complete lines. No expense has been spared in the matter of apparatus for teaching or research work, and the facilities for practical study in these subjects are as excellent as all the other arrangements of the school.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum, which is open daily. In addition, there is a museum devoted to *materia medica* specimens, and a large library and reading room. There are a number of recreation, athletic, and other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms both for men and women students. In the university buildings there is a refectory open to all students of the school, and a university journal, *Floreamus*, edited by a joint committee of the staff and

students, is published each term. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide over 500 beds for the treatment of medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them; whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at either institution by the anaesthetists, and the *post-mortem* examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students also have the advantage of being able to attend the practice of the Jessop Hospital for Diseases of Women and the Hospital for Sick Children, while special courses on fever are given at the City Fever Hospital, and on mental diseases at the South Yorkshire Asylum.

Appointments.—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) Casualty dresserships, (2) surgical dresserships, (3) medical clerkships, (4) pathological clerkships, (5) ophthalmic clerkships, (6) clerk to the skin department, etc. Except in the case of casualty dressers, these appointments are made for three months, commencing on the first day of October, January, April, and July. The casualty dresserships last two months, beginning on the first of any month. All students are required to hold them, and to have attended the tutorial classes for casualty dressers, before being eligible for any other of the above appointments.

Scholarships.—Entrance Medical Scholarship, value about £130, open to both sexes. Four Edgar Allen Scholarships of £100 a year for three years may be held by students taking the degree course in Medicine. Two Town Trustees' Scholarships, each of the value of £50, tenable for three years, for boys or girls under the age of 19 years who have been educated in a Sheffield secondary school for a period not less than two years immediately preceding the examination. Four Town Trustees' Scholarships, value £50, for boys or girls under 19 years of age, educated in any school in Sheffield, secondary or otherwise. Town Trustees' Fellowship, value £75, tenable for one year. Mechanics' Institute Fellowship, value £50 (with remission of fees), tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50, tenable for two years. Kaye Scholarship, for proficiency in anatomy and physiology, value £22 10s. Gold and bronze medals are also awarded for proficiency in various subjects.

Fees.—The composition fee of £80, payable in three instalments, covers attendance on all the courses of lectures and practical classes, except pharmacy, required for a degree course in the university, or for the ordinary qualifications in medicine and surgery of the Examining Boards. It does not include hospital practice, the fee for which is £49 17s. 6d., payable in three instalments.

SCOTLAND.

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of its different medical centres is in some cases added an account of hospitals which either play an official part in the education given to students as yet unqualified or offer valuable opportunities for post-graduation work.

ABERDEEN.

The school is conducted by the Faculty of Medicine. This comprises twelve chairs, from which instruction is given in all the main branches of medical science—namely, botany, zoology, physics, chemistry, anatomy, physiology, *materia medica*, pathology, forensic medicine, surgery, medicine, and midwifery. Courses of instruction in public health and in tropical medicine are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to the departments.

Clinical instruction is obtained in the Royal Infirmary

(accommodating 270 patients), the Royal Lunatic Asylum (900 patients), the Sick Children's Hospital (85 patients), the City Fever Hospital (250 patients), the General Dispensary, Maternity, and Vaccine Institution (10,000 out-patients annually), and the Ophthalmic Institution (3,000 patients annually). Courses of practical instruction are given in diseases of children at the Sick Children's Hospital; in fevers at the City Fever Hospital; in insanity at the Royal Asylum; in diseases of ear, nose, and throat at the Infirmary and Dispensary; in diseases of the eye at the Infirmary and Eye Institution; in diseases of the skin at the Royal Infirmary.

Bursaries.—Scholarships and Fellowships, to the number of fifty and of the annual value of £1,180, may be held by students of medicine in this university. They range from £8 to £100 per annum, and are tenable in most cases for two or three years.

Fees.—The fee for each university course is, as a general rule, £4 4s.; and for a second attendance, £3 3s. An inclusive fee of 90 guineas is now payable, covering the necessary instruction within the university. Matriculation fee, both sessions, £1 1s.; summer session alone, 10s. 6d. Royal Infirmary, perpetual fee, £10; or, first year, £5 10s.; second year £5. The winter session begins on October 11th.

EDINBURGH.

THERE are three Schools of Medicine: the School of the University, the School of Medicine of the Royal Colleges, Edinburgh, and the Edinburgh School of Medicine for Women.

THE UNIVERSITY SCHOOL.—This school, in addition to other resources of the university, has the following means of affording practical instruction: Royal Botanic Garden, Herbarium, and Museum; Zoological Laboratory and Museum of Science and Art; Physical Laboratory; Chemical Laboratories; Dissecting Room, Bone Room, and Anatomical Museum; Physiological Laboratory; Medical Jurisprudence Laboratories; John Usher Institute of Public Health; Materia Medica Museum and Laboratory; *Post-mortem* Department of the Royal Infirmary and University Pathological and Bacteriological Laboratory; Tutorial Classes of Practice of Physic, of Clinical Medicine, and Clinical Surgery, Surgery, and Midwifery; and the practice of certain other hospitals.

Fees.—The sessional fee for zoology, botany, chemistry, anatomy lectures, physiology, pathology, materia medica, medical jurisprudence, surgery, medicine, midwifery and gynaecology is £4 4s. each. Second course £3 3s. Third free. A perpetual ticket taken at the beginning of the first year is £6 6s. Physics, practical chemistry, advanced practical physiology, practical pathology, practical anatomy (winter), operative surgery, obstetric operations, practical materia medica, including pharmacy, pathological bacteriology, experimental pharmacology, vertebrate morphology and comparative embryology, are £3 3s. Clinical surgery, £2 2s. per term. Clinical medicine, first term, £3 13s. 6d.; subsequent terms, £2 2s. No perpetual ticket in these subjects. Practical botany (besides garden fee of 5s.), elementary practical zoology, practical physiology (experimental), practical physiology (histological), practical botany (advanced), practical zoology (advanced), practical anatomy (summer), anthropology, anatomy, demonstrations, diseases of children, diseases of the eye, diseases of the larynx, ear, and nose; diseases of tropical climates, clinical instruction on diseases of the skin, regional anatomy, physiological, chemistry, invertebrate zoology, organic chemistry, mental diseases, £2 2s. Applied anatomy (medical and surgical), £1 1s. Vaccination, £1 1s.

Scholarships.—There are many funds for the assistance of students by means of bursaries, scholarships, exhibitions, and money awards from the beginning to the end of their undergraduate career. In addition there are funds which help those who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards, and the conditions attaching to them, are so varied that those interested should consult the prospectus of the school itself. No other university is in a better, even if in as good, a position to smooth the financial path of earnest students.

THE SCHOOL OF MEDICINE OF THE ROYAL COLLEGES.—This school is composed of lecturers licensed by the Royal College of Physicians and the Royal College of Surgeons, and also recognized by the university through their *licentia docendi*; for the sake of convenience they lecture in separate buildings near to the Royal Infirmary, but form a single corporate body governed by a board consisting of five members elected by the Royal College of Physicians, of five members elected by the Royal College of Surgeons, and of five members elected by the lecturers in the school. This board, with the assistance of the standing committees of the school, supervises the whole management, and especially the maintenance of the efficiency and discipline of the school. The different buildings at present utilized for the purposes of lecturing are the following: (1) Surgeons' Hall, Nicolson Street; (2) New School, Bristo Street; (3) Nicolson Square; (4) Marshall Street; and other places. The teaching is similar to that of the Scottish universities, and the students receive similar certificates at the close of each session. The courses on the special subjects not included in the curriculum of the Examining Boards are also conducted by teachers specially qualified in each branch, and have for the last quarter of a century formed a special feature of the school. The fees payable for class and other instruction, and including the sums payable on admission to the examination of the Conjoint Board for the triple qualification, amount to about £120. The Calendar, giving full information regarding classes and fees, can be obtained gratis on application to Major D. G. Marshall, I.M.S., Dean of the School, 11, Bristo Place, Edinburgh.

WOMEN STUDENTS IN EDINBURGH.—Until the close of the summer session of 1916 women students intending to proceed to graduation in the University of Edinburgh, as well as those entering for the triple qualification of the Royal Colleges of Edinburgh and Glasgow, received their training in the Edinburgh School of Medicine for Women. Now women students study under the same conditions as men, and may obtain either the university degree or the diploma of the Royal Colleges. In the university systematic lectures are given to them by the professors in the ordinary classes, which are therefore mixed; but in two subjects, namely, midwifery and gynaecology and materia medica, the women are lectured to separately from the men. All the practical classes are taught to men and women separately save in a few advanced classes. The women students also have the same privileges as in the past have been given to the men of attending a certain proportion of the extramural classes taught by the lecturers of the School of Medicine of the Royal Colleges.

GLASGOW.

THERE are five medical schools in this city: The two schools of the university, one of which (Queen Margaret College) is for women students; St. Mungo's College (the school of the Royal Infirmary), Anderson's College, and the Western Medical School.

THE UNIVERSITY SCHOOL FOR MEN.—The whole course of study required for graduation (M.B., Ch.B.) at the University of Glasgow can be taken here. Besides ample provision for lectures there is practical and clinical work at the hospitals, and practical courses are conducted in the laboratories of the following departments: Surgery, Pathology, Public Health, Pharmacology, Physiology, Anatomy, Chemistry, Zoology, Physics, and Botany; the Botanic Garden and the Hunterian Museum (Zoology and Pathology) are also open to students. New buildings and equipments have been provided for botany, for practical anatomy, for operative surgery, as well as for pathology; the very large additions made a few years ago to the Chemical Laboratory rendered it one of the most extensive in Scotland. The class-rooms and laboratories for the departments of Physics, Physiology, Pharmacology and Materia Medica, and Medical Jurisprudence and Public Health, are also of recent erection, and are elaborately equipped. Four additional chairs of Medicine, Surgery, Obstetrics, and Pathology have been recently established, the Professors being specially attached to the Royal Infirmary; and a number of University Lectureships in Clinical Medicine, Clinical Surgery, Venereal Diseases, Laryngology, Dermatology, Otolaryngology, and Psychological

Medicine have been founded there. The university, in short, has made great and successful efforts to extend and improve the accommodation of the medical departments, to strengthen the teaching staff, and to encourage post-graduate and research work. Three very extensive general hospitals in the city afford exceptional opportunities for clinical instruction—namely, the Western Infirmary (600 beds), near the university, to which the Regius Professors are attached; the Royal Infirmary (630 beds); and the Victoria Infirmary (260 beds); while the Royal Asylum (460 beds), the Royal Hospital for Sick Children (200 beds), the Royal Maternity and Women's Hospital (108 beds), the Glasgow Eye Infirmary (100 beds), the Ophthalmic Institution (35 beds), the fever hospitals at Belvidere (680 beds) and Ruchill (540 beds), and other institutions afford facilities for the practical study of special branches. In each year, since the beginning of the war, special qualifying examinations in Medicine, Surgery, and Midwifery have been held, in order that candidates who had completed their full curriculum might be enabled to graduate without delay. Practically all the successful candidates have received commissions in the R.A.M.C.

Bursaries.—Bursaries confined to the Medical Faculty amount in annual value to about £1,000, while bursaries in any faculty amounting to about the same annual sum, may be held by students of medicine, a number of both sets being open to women. Several valuable scholarships may be held by medical students who have graduated in Arts. Some of the bursaries are described below.

Fees.—The matriculation fee for each year is £1 1s. In most cases the fee for each university class is £4 4s., but in some cases it is £3 3s. For hospital attendance students pay an entrance fee of £10 10s. at the Western Infirmary, with an additional fee of £3 3s. for each winter and £2 2s. for each summer clinical course; at the Royal Infirmary the fees are somewhat similar. The university fee for the four professional examinations is £23 2s. (£6 6s. each for the first and second examinations, and £5 5s. each for the third and fourth). For the whole curriculum the fees for matriculation, class attendance, hospital attendance, and professional examinations amount to £150.

For further information apply to the Registrar, Glasgow University.

Bursaries.—The following bursaries are open to undergraduates of both sexes: The Gibson Bursary, annual value £36, tenable for four years. This is open to medical students who are preparing for service as medical missionaries in connexion with the Church of Scotland, and will be awarded to the eligible candidate who has gained the highest number of marks in the First Professional Examination. One Logan Bursary, annual value £16, tenable for four years; appointment by the Senate. The Mackintosh Mental Science Bursary in medicine, of the value of £31, is awarded annually to the student (of either sex) attending the class of insanity who stands first in an examination in that subject, the bursar to continue the practical study of the subject to the satisfaction of the Faculty of Medicine. The Gardiner Bursary, annual value £14, tenable for two years, will be awarded after the autumn professional examination to the candidate who has passed in physiology at the Second Professional Examination, and whose aggregate of marks in that subject and in chemistry and physics of the First Professional Examination is the highest. The following are tenable in any faculty: Two Pratt Bursaries (each £20 and tenable for four years); and two Taylor Bursaries (each £10 and tenable for four years). Andrew and Bethia Stewart Bursaries (£50 each, tenable for three years); candidates must have taken the M.A. degree of Glasgow. There is a special examination. Nine Glasgow Highland Society's Bursaries, for students of Highland descent, of the annual value of £25, and tenable for five years; two vacant each year. The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction, under conditions given in the *University Calendar*. The Dobbie Smith Gold Medal is awarded for the best essay on a prescribed subject within the science of botany. The Brunton Memorial Prize of £10 is awarded annually to the most distinguished graduate in medicine of the year. The University Commissioners issued an ordinance to make regulations for the admission of women to certain bursaries, scholarships, and fellowships. Scholarships and Fellowships are offered by the Carnegie Trust in science and medicine for post-graduate study. There are also four McCunn Medical Research Scholarships (£100 for one year) for graduates in medicine of the Scottish universities.

QUEEN MARGARET COLLEGE.—In this, the Women's Medical School of the University of Glasgow, the courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have their own buildings, with

class-rooms, reading-room, library, etc. They are taught in some classes apart from male students, in others together with them, but in either case have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, where wards containing 520 beds are available for their use, and in its dispensary; also in the Royal Hospital for Sick Children, the Glasgow Ear Hospital, the Royal Asylum, Gartnavel; the Ophthalmic Institution, the City of Glasgow Fever Hospitals, Belvidere and Ruchill; and the Glasgow Royal Maternity and Women's Hospital.

Scholarship.—The Arthur Scholarship, annual value, £20, tenable for three years. Open to competition by medical students of first year at the First Professional Examination in October each year. This scholarship is the gift of Mrs. Arthur, of Barshaw, and is restricted to women medical students.

Board for Students.—A house of residence for women students, Queen Margaret Hall, is situated near the college. The cost of board and residence is from 19s. to 27s. per week, according to accommodation. Full information can be obtained from the Mistress, Queen Margaret College, or from the Lady Superintendent, Queen Margaret Hall, Bute Gardens, Glasgow.

ST. MUNGO'S COLLEGE.—This is the Medical School of the Royal Infirmary, which is the largest in Glasgow. The infirmary is situated in Cathedral Square, Castle Street, and has car communication with every part of the city. St. Mungo's College is in the infirmary grounds.

The infirmary has (including the ophthalmic department) over 660 beds, the average number occupied in 1916 being over 600. There are special beds and wards for diseases of women, of the throat, nose, and ear, venereal diseases, burns, and septic cases. In the out-patient department the attendances in 1916 numbered over 180,000. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion, and year by year the latest and most approved apparatus for diagnosis and treatment is added.

Appointments.—Five house-physicians and ten house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As many cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

Fees.—The average class fee is £2 2s. The fees for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £70. The classes are open to male and female students.

THE ANDERSON COLLEGE OF MEDICINE.—This school provides education in all subjects of the curriculum both for medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the entrance of the Western Infirmary, within two minutes' walk of that institution and four minutes' walk of the university. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary; pathology in the Western or Royal Infirmary; vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, and also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions which are stated in the school Calendar). The courses (lectures and laboratory) in public health are also recognized by the Scottish Licensing Board, Queen's University of Belfast, the Irish Colleges, and the University of Cambridge.

Fees.—The fees for the lectures and practical work required by ordinary students range between 1 and 5 guineas a session. In the Public Health Department the fee for a six months' course is £12 12s. The Carnegie Trust pays the fees of students at Anderson's College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a post-card by the Secretary to the Medical Faculty, the Anderson College

of Medicine, Glasgow, W., who will forward any further information which may be desired.

GLASGOW WESTERN MEDICAL SCHOOL.—This school has been closed until after the war.

ST. ANDREWS AND DUNDEE.

THE medical departments in these two teaching centres cater specially for students proceeding to the degrees of the University of St. Andrews, but admit other students as well. In the former city the United College provides education in all subjects of the first two years. In Dundee, University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain fully equipped laboratories. The clinical work of the school is facilitated by various institutions. The class fees are 4 guineas for systematic classes, and 3 guineas for practical classes. The hospital ticket is £1 ls. for three months, £3 3s. a year, or perpetual £10 in one sum or £10 10s. in instalments. Added up, the fees for the curriculum, exclusive of the examination fees, amount to £136 10s. In connexion with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St. Andrews. Information regarding the clinical facilities may be obtained from Professor Kynoch, Dean of the Medical Faculty, Medical School, Dundee.

Clinical Work.

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary, the instruction given thereat being recognized for purposes of graduation by all the Scottish universities, the University of London, the university of Cambridge, the National University of Ireland, and by the Royal Colleges of England and Scotland.

IRELAND.

THERE is a choice of six schools for those prosecuting their medical studies in Ireland, and for clinical instruction the choice is equally satisfactory and varied, though the hospitals themselves are comparatively small. Some account of the schools follows.

DUBLIN.

The School of Physic.

This school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and of the Royal College of Physicians in Ireland; the King's professors of institutes of medicine (physiology), practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at Sir Patrick Dun's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board. The courses of instruction are open to all medical students whether or not they belong to the university. A three weeks' post-graduate course is given each autumn, and covers all departments of medicine and surgery. Information concerning the post-graduate course can be obtained from Dr. Alfred Parsons, 27, Lower Fitzwilliam Street, Dublin.

A special Final Examination will be held on September 11th, 1917, for students who have at least five years' credit for attendance in the school and who are volunteering for active service in connexion with the war.

The Schools of Surgery.

These are schools carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the college's own school, combined with two famous old medical schools—Carmichael and Ledwich; they are attached to the college by charter. The buildings contain spacious dissecting rooms, one set apart for lady students, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the college.

Prizes.—Among the prizes annually awarded are: The Barker Anatomical Prize (£25 5s.) the Carmichael Scholarship (£15);

the Mayne Scholarship (£8); the Gold Medal in Surgery, and the Stoney Memorial Gold Medal in Anatomy; class prizes of £2 and £1, accompanied by silver medals, will also be given in each subject.

The next session begins October 15th. A prospectus can be obtained post free on application to Mr. Alfred Miller, Registrar, Royal College of Surgeons, Dublin.

University College.

This is one of the constituent colleges of the National University of Ireland, and at present conducts its work at buildings on St. Stephen's Green, at those formerly occupied by the Cecilia Street School of Medicine, and at the University Buildings in Earlsfort Terrace. All the buildings of its permanent home are not yet ready. The section of the new college buildings at Earlsfort Terrace for the departments of physics and chemistry, and new laboratories for pathology are now in use. It possesses a good library, and the arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. The teaching staff is numerous, and through it the college is connected with many of the hospitals of the city. Students, however, are allowed to pursue their studies at any of the hospitals recognized for the purpose by the university.

Clinical Work.

There are numerous well-arranged hospitals in and around the city, and almost all of these are recognized for teaching purposes by the Conjoint Board of Ireland, the University of Dublin, the National University of Ireland, and by like bodies elsewhere in the United Kingdom. Among them are the Mater Misericordiae Hospital, with 345 beds; Dr. Steevens's Hospital at Kingsbridge, with 200; Meath Hospital and County Dublin Infirmary, with 160; Mercer's Hospital, close to Trinity College, with 120; the Royal City of Dublin Hospital, with 124; the Adelaide Hospital, with 140; the Royal Victoria Eye and Ear Hospital, with 100 beds; Sir Patrick Dun's, which has a direct connexion with the School of Physic, and the combined institutions formed by the Hardwicke Fever Hospital, the Richmond Surgical Hospital, and the Whitworth Medical Hospital, with an aggregate of 230 beds. As for that known as the Rotunda Hospital, this practically consists of two distinct hospitals, and is believed to be the largest combined maternity and gynaecological hospital in the United Kingdom. It receives nearly 3,000 patients every year, and, apart from ordinary out-patient work of a gynaecological order, annually attends approximately 2,000 women at their own homes during their confinement. It possesses residential quarters for students, and, taken as a whole, offers exceptional opportunities for study both to ordinary students and to post-graduates of any nationality.

BELFAST.

THE Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in connexion with the departments of biology, chemistry, physiology, pathology, anatomy, physics, and materia medica are all excellent, and there is a Students' Union which gives students the advantage of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago and has 300 beds, and the Mater Infirmorum Hospital, which has 150 beds. Other hospitals open to the students of the university are: The Maternity Hospital the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital; the Benu Ulster Eye, Ear, and Throat Hospital; the Union Infirmary and Fever Hospital; the Fever Hospital, Purdysburn; the District Lunatic Asylum, the Samaritan Hospital, Forster Green Hospital for Diseases of the Chest, and the Belfast Hospital for Skin Diseases.

Scholarships.—(1) Twelve, of the value of £40 each, are assigned as Entrance Scholarships in the Faculties of Arts, Science, and Medicine, tenable for one year; (2) sixteen Professional Scholarships, value from £15 to £40 each; (3) one Hutchinson Stewart Scholarship, £12, in mental diseases; (4) one Mackay Wilson Travelling Scholarship, £100, awarded triennially; (5) Isabella Tod Memorial Scholarship, tenable for three years, awarded triennially to a woman student; (6) Magrath Clinical Scholarship, awarded annually, value about £112; (7) numerous

sessional prizes. There is also a post-graduate research fund, open to all graduates of not more than three years' standing. Gold medals are awarded at the M.D. examination.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £120. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital, but not fees for the special hospitals. The course for the Conjoint Board costs about the same amount. The Calendar containing full information can be obtained on application to the Secretary, Queen's University, Belfast, price 1s.

UNIVERSITY COLLEGE, CORK.

THIS institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the new National University. It holds examinations for all the faculties of that university, in addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the new university, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, the Society of Apothecaries of London, or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmaries (each 100 beds) and at the Cork Union Hospital (1,200 beds). Students can also attend the Mercy Hospital (60 beds), the County and City of Cork Lying-in Hospital, the Maternity, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglington Lunatic Asylum. The session extends from October to June.

A Dental School has been started within the last four years, in which the degree of Bachelor of Dental Surgery of the National University of Ireland is granted. There is a large, well-equipped Dental Hospital in connexion with the School.

Scholarships.—Over £4,000 are available annually for scholarships in the college. Particulars as to each of them can be obtained on application to the Registrar.

Fees.—The fees for the lectures and hospital attendances required by the National University of Ireland course, including examination fees, come to about £120. Further information can be found in the college regulations, or obtained on application to the Registrar.

UNIVERSITY COLLEGE, GALWAY.

THIS institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Arts, Celtic, Science, Law, Engineering, Commerce, and Medicine. Candidates for degrees in medicine must reside for three years. For the remaining two years certificates from any recognized medical school are accepted. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it, and there are many arrangements, such as a library and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National Universities, but for those of London University and the diplomas of the various colleges in the three kingdoms, is carried on at the Galway County Hospital, the Galway Union Hospital, and the Galway Fever Hospital. The former is a general hospital, and at the two latter students have ample opportunities of studying zymotic and chronic diseases. The Union Hospital has a special ward for diseases of children. Each year the Governing Body offers about £1,500, and the County Councils of Connaught offer about £3,500, in scholarships. These scholarships are tenable in any Faculty. Additional information regarding these scholarships can be obtained on application to the Registrar, and to the Secretaries of the Connaught County Councils.

CLINICAL HOSPITALS IN ENGLAND.

THERE are a great many hospitals in the United Kingdom which, though not connected with any medical school, open their doors either to those who have yet to become qualified, to those who are doing post-graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving such instruction as opportunity offers, and at those which are situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer intervals, appointments for resident medical officers, house-physicians, and house-surgeons. These are usually paid offices, which may be held for periods varying from six months to a year. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in these localities, but it should be added that there are many other provincial hospitals where admirable work is done, and at which much valuable experience can be gained by both senior and junior students, and by those already admitted to the *Medical Register*. Cases in point are the Royal Infirmary, Bradford; the Royal Sussex County Hospital, Brighton; the Royal United Hospital, Bath; the Kent and Canterbury Hospital; Derbyshire Royal Infirmary; the Royal Albert Hospital and Eye Infirmary, Devonport; the Royal Devon and Exeter Hospital; the West of England Eye Infirmary, Exeter; the Gloucestershire Royal Infirmary and Eye Institution; the Royal Infirmary, Leicester; the County Hospital, Lincoln; the General Hospital, Northampton; the Norfolk and Norwich Hospital; the General Hospital, Nottingham; the Royal Portsmouth Hospital; the Royal South Hants and Southampton Hospital; the Staffordshire General Infirmary, Stafford; the North Staffordshire Infirmary at Hartshill; the Royal Hants County Hospital, Winchester; the Wolverhampton and Staffordshire General Hospital; and the County Hospital, York. As for hospitals in the metropolis, so many of these play the part of clinical schools that it is worth while to classify them.

General Hospitals.—These include the Dreadnought Hospital at Greenwich, and its annexe at the Albert Dock, which form the head quarters of the London School of Clinical Medicine and the London School of Tropical Medicine; the West London Hospital and the Prince of Wales's General Hospital, Tottenham, both of these being described in the article on post-graduate work; the Great Northern Central Hospital, Holloway Road, an institution containing 185 beds; and the Temperance Hospital in Hampstead Road.

Children's Hospitals.—There are at least seven of these, the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 240 beds. There are also the East London Hospital for Children, Shadwell, with 124 cots; the Queen's Hospital for Children, Bethnal Green, with 134; the Victoria Hospital for Children, Chelsea, with 104; the Belgrave Hospital for Children, which has a considerable out-patient department, but in-patient accommodation for only 40 children; the Paddington Green Children's Hospital, an institution of about the same size; and the Evelina Hospital for Sick Children, Southwark Bridge Road, with 76 beds.

Hospitals for Women.—These include Queen Charlotte's Lying-in Hospital, which specializes in the teaching of midwifery; the Samaritan Hospital for Women, Marylebone Road, to which qualified practitioners are admitted as clinical assistants to both the in-patient and out-patient departments. Demonstrations are given daily in both departments, the fees—payable in advance—being £3 3s. for three months. Full particulars may be obtained on application to the secretary at the hospital. In addition may be mentioned the Hospital for Women, Soho Square; the Chelsea Hospital for Women, Arthur Street, Chelsea; and the New Hospital for Women in Easton Road, the latter being in the nature of a general hospital so far as concerns the class of case treated.

Eye Hospitals.—The largest of these is the Moorfields Eye Hospital, City Road, with 138 beds and a very large out-patient department; others are the Royal Westminster Ophthalmic Hospital, near Charing Cross, the Royal Eye

Hospital, Southwark, each with about 40 beds; and the Central London Ophthalmic Hospital, Judd Street, W.C.1, with 28.

Fever Hospitals.—The Metropolitan Asylums Board has under its control a good many institutions for the treatment of the more serious zymotic disorders, and makes special arrangements for the instruction of students in this subject, and grants certificates at the end of the courses. Detailed information should be sought from the Clerk to the Board, Victoria Embankment.

Chest Hospitals.—The largest of these is the Brompton Hospital for Consumption, which has 333 beds and a large sanatorium at Frimley with 150 beds. There is also the City of London Hospital for Diseases of the Chest, Victoria Park, with 175 beds, and the Royal Hospital for Diseases of the Chest, City Road, which has recently reorganized its various departments with the object of better fitting itself to act as a tuberculosis school.

Nose, Throat, and Ear Hospitals.—The institutions which confine their work to disorders of the throat, nose, and ear all make special arrangements for the benefit of senior and post-graduate students. They are the Metropolitan Ear, Nose, and Throat Hospital, Fitzroy Square; the Royal Ear Hospital, Dean Street; the Central London Throat and Ear Hospital, Gray's Inn Road; and the Hospital for Diseases of the Throat, Golden Square—the latter, which possesses 75 beds, being the largest of the four institutions.

Miscellaneous Special Hospitals.—Among these are the Bethlehem Royal Hospital, Southwark, which confines its work to the treatment of mental diseases; St. Peter's Hospital for Stone and Urinary Diseases, Henrietta Street, Covent Garden; St. Mark's Hospital, City Road, which devotes itself to the treatment of diseases of the rectum, including cancer and fistula; St. John's Hospital for Diseases of the Skin, in Leicester Square; the Hospital for Diseases of the Skin, Stamford Street, Blackfriars; and the National Hospital for the Paralysed and Epileptic, Queen Square, W.C.1, an institution possessing 200 beds and a world-wide reputation.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to their secretaries.

MEDICAL EDUCATION OF WOMEN.

WOMEN are admitted to the medical examinations of the following qualifying bodies: All the universities of Great Britain, with the exception of Oxford and Cambridge; the Royal College of Physicians, London, and the Royal College of Surgeons, England; the Society of Apothecaries of London; the Conjoint Colleges of Scotland and of Ireland.

The regulations of each differ considerably, so that it is necessary for a student to decide, before beginning her course, which degree or diploma she will aim at obtaining. The ordinary regulations of the General Medical Council (see page 311) must be observed, and women can pursue their education either at certain schools only open to women, or at ordinary schools where they do their work more or less in common with men students.

The schools which admit women only are the London (Royal Free Hospital) School of Medicine for Women, which is one of the constituent schools of the Medical Faculty of the University of London, and Queen Margaret College, Glasgow (see page 335). Women are also admitted to the schools of medicine conducted in connexion with King's College, London; the Universities of Dublin, Dundee, Durham, Liverpool, Manchester, Birmingham, Leeds, Sheffield, Bristol, and Aberdeen; St. Mungo's College, Glasgow, the Schools of Surgery of the Royal College of Surgeons in Ireland and of the National University of Ireland in Dublin, Cork, and Galway. The arrangements for women medical students in Edinburgh are indicated on page 334. Women can also attend classes for the first three years of the medical curriculum at University College, Cardiff.

Year by year the openings for women who adopt a medical career have increased, and the field open to their energies is now wide. Women hold many appointments as resident medical officers in general hospitals and in hospitals for women and children all over the country, and

in a large number of sanatoriums, infirmaries, fever hospitals, and asylums. Many medical women are also engaged in public health and school inspection work.

As regards the London School of Medicine for Women, particulars will be found at p. 329 in the article on London Medical Schools.

DEGREES FOR PRACTITIONERS.

At one time it was almost the universal custom for medical students educated in London not to seek a university degree, and as that custom still prevails to a considerable extent, a very large proportion of medical men in actual practice in England possess diplomas to practise but not degrees in medicine. This is a fact which they sometimes find reason to regret, and to such practitioners the following paragraphs may be of interest. It should be noted that the M.D. degree of the University of Brussels is not registrable when it has been obtained subsequently to June, 1886, but this fact does not lessen its value to those who see any utility in possessing a degree as well as a registrable diploma.

UNIVERSITY OF LONDON.

Registered medical practitioners who have passed the First Examination for medical degrees and the Second Examination for medical degrees, Part I, may proceed to the Second Examination for medical degrees, Part II, and M.B., B.S. Examinations without observing the intervals prescribed by the regulations, on producing certificates that they have gone through the required course of study at a school of the university; subject to the proviso that no degree of the university can in any circumstances be granted by examination to any one in less than three years after passing the Matriculation Examination or after admission by the university of the candidate's right to exemption therefrom.

UNIVERSITY OF DURHAM.

The degree of M.D. is granted by the University of Durham to registered practitioners of not less than fifteen years' standing, who have been qualified and in practice for that period, upon the following conditions without residence: The candidate must be 40 years of age, and must produce a certificate of moral character from three registered medical practitioners. Should he not have passed an examination in arts previously to the professional examination in virtue of which his name was placed on the Register, he is examined in classics and mathematics; if otherwise he is required to translate into English passages from any one of the following Latin authors: Caesar, *De Bello Gallico* (first three books), Virgil, *Æneid* (first three books), or Celsus (first three books).

Professional Examination.—The candidate must pass an examination in the following subjects: (i) Principles and practice of medicine, including psychological medicine, hygiene, and therapeutics; (ii) principles and practice of surgery; (iii) midwifery and diseases of women and children; (iv) pathology, medical and surgical; (v) anatomy, medical and surgical; (vi) medical jurisprudence and toxicology. The examination is conducted by means of printed papers, clinically, and *viva voce*, at the College of Medicine, Northumberland Road, Newcastle, and in the Royal Victoria Infirmary, Newcastle. The classical portion of the examination may be taken separately from the professional on payment of a portion (£10 10s.) of the full fee.

Foreign and Colonial Practitioners.—Natives of India or the British Colonies are placed on the same footing as natives of Great Britain. Natives of India must produce evidence from an Indian university that they have passed within one year an examination in Latin.

Fees.—The inclusive fee is 50 guineas; if a candidate fail to pass, 20 guineas are retained, but if he present himself again, 40 guineas only are required.

Dates, etc.—The examinations are held twice a year, towards the end of March and of June. Notice, accompanied by the fee and certificates, must be sent to Professor Howden, Secretary of the University of Durham College of Medicine, Newcastle-on-Tyne, at least twenty-eight days before the commencement of the examination.

UNIVERSITY OF BRUSSELS.

This university grants its M.D. to such foreign candidates as are already duly qualified in medicine and surgery in their own countries, provided they pass the three examinations imposed. Information can be obtained either from the Secretary of the University, 14, Rue des Sols, Brussels, or from Dr. Arthur Haydon, Honorary Secretary of the Brussels Medical Graduates' Association, 11, Welbeck Street, Cavendish Square. The examinations for the degrees are still going on at the University of Brussels, but for internal students only at present during the German occupation. This is due to the mobilization of the examining staff with the Belgian army.

POST-GRADUATION STUDY.

THE value, and in some circumstances even the necessity, of post-graduation study is now so generally recognized that there is no occasion to dilate upon it here. The need for some means of acquiring direct knowledge of the technique of the new branches which are constantly springing up is indeed so generally felt among otherwise experienced practitioners that several institutions designed solely for their benefit have been at work now for some years. Of these institutions some account follows. Beyond this it need merely be said that in normal times most medical centres hold one or more courses for qualified men during the year; that most of the institutions mentioned in the section on Clinical Hospitals make special arrangements for the benefit of qualified men desirous of studying work of the kind undertaken within their wards; and that valuable adjuncts to post-graduation study exist in the shape of the Library of the British Medical Association—one specially rich in recent works—of the libraries of the several universities, and in those of the Royal College of Surgeons of England and of the Royal College of Physicians in London and in Edinburgh.

WEST LONDON POST-GRADUATE COLLEGE.

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895, and the present building was opened in 1901; it is provided with lecture, reading, writing, and class rooms, and accommodation of all sorts for the convenience of post-graduate students. In the five years before the war the yearly entry has averaged over 220. The work of the college is eminently suitable for men taking up war work.

As for ward work, the students accompany the senior staff on their visits to the wards at 2.30 p.m. daily, and also go round with the resident medical officers in the morning. Out-patient work begins at 2.15 p.m. This department is large, and affords ample facilities for post-graduates to see and examine patients. There are the usual special departments dealing with diseases of the eye, ear, throat, nose, skin, orthopaedics, x-ray work, electro-therapeutics, gynaecology, and mental diseases of children. Post-graduates are appointed to act as clinical assistants for three or six months. There is no charge to members of the college. Practical classes are held in medicine, general practical surgery, gastro-intestinal surgery, surgical diseases of children, analysis of blood and urine, cystoscopy, venereal disease, tropical diseases, retinoscopy, ophthalmic operative surgery, and, when material is available, in operative surgery. The size of the classes is limited so as to ensure that each student shall have full opportunities of gaining experience in methods of examination and treatment.

A special clinic for the treatment of diseases of the skin and genito-urinary organs (male and female) is held every evening (Saturdays included) at 5.30 p.m. Post-graduates are admitted to the work of the clinic free, and certificates of satisfactory attendance and work are given.

Operations take place at 2 p.m. daily, the surgeons often availing themselves of the assistance of the post-graduates, and in any case making arrangements so that they can readily see what is going on. The anaesthetists give instruction in the administration of different anaesthetics, including spinal analgesia, on the operating days, students being allowed to administer them under supervision, while special classes are held in each session.

The pathological laboratory is in charge of a pathologist who attends every day. In bacteriology and microscopy special instruction is given on three mornings a week, the students working at other times under the general guidance of the pathologist.

Demonstrations are given every day in the morning by the assistant physicians, assistant surgeons, and by the medical and surgical registrars in practical medicine and surgery. Lectures of a practical kind are given daily (except Saturday and Sunday) at 5 p.m. During the war, however, class demonstrations and lectures are discontinued.

The fees are as follows: Hospital practice, including all ordinary demonstrations and lectures, £1 1s. for one week, £3 3s. for one month, £4 4s. for six weeks, £6 6s. for three months, £10 10s. for six months, £15 15s. for one year, and £30 for a life ticket. Every year in August there is a special vacation class lasting four weeks, for which the fee is £3 3s. Three months' instruction in the administration of anaesthetics costs £5 5s. Subscriptions for any course can be taken out from any date. The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the India Office, and the University of London (for higher degrees).

A prospectus concerning the school can be obtained on application to the Dean.

LONDON SCHOOL OF CLINICAL MEDICINE (POST-GRADUATE),
DREADNOUGHT HOSPITAL, GREENWICH, S.E.10.

The school buildings, lecture rooms, operative surgery class-rooms, pathological laboratories, museum, library, etc., are in the Seamen's Hospital at Greenwich. The whole hospital of 250 beds, with its out-patient department, is open to students from 10 a.m. till 5 p.m.

At present the regular courses are in abeyance in consequence of the war, but a certain amount of pathology and operative surgery is still done. In normal times medical, surgical, and special department in-patient clinics are held every afternoon except Saturday by the senior members of the staff, whilst out-patients are demonstrated daily in the forenoon in the medical, surgical, and special departments by the assistant physicians and surgeons. Practical classes are arranged each session in the following subjects: The practice of medicine, diseases of the nervous system, medical diseases of women, medical diseases of children, diseases of the skin, practice of surgery, operative surgery, diseases of the eye; diseases of throat, nose, and ear; surgical diseases of women, midwifery and gynaecology, surgical diseases of children, pathology, clinical pathology, bacteriology, surgical and medical pathology, hygiene and public health; anaesthetics, skiagraphy, and mental diseases.

Two sessions of five months (October-February) and four months (April-July), are held in each year. The session's work is arranged so as to enable individual students to join the demonstrations, etc., at any time during the session.

Affiliated to the London School of Clinical Medicine for the purposes of extension of the variety of clinical material and teaching are the Royal Waterloo Hospital for Children and Women, the Miller General Hospital, Greenwich, and the Bethlem Royal Hospital for Mental Diseases. These hospitals are directly linked to the Dreadnought both by rail and by tram. The supply of material affords exceptional facilities for practical instruction in operative surgery and in pathology. There is also a wide field for the study of venereal diseases, on which special clinics are given, and there is a department with open-air wards for the treatment of tuberculosis. Every variety of disease may be studied in the wards and out-patient rooms of the Dreadnought Hospital and at the affiliated hospitals. The certificates of the school are recognized by the University of London (for the higher degree), the Admiralty and the War Office, the India Office, and the Colonial Office.

Appointments.—There are a medical superintendent, surgical and medical registrars, two house-physicians, and two house-surgeons at the Dreadnought Hospital, Greenwich. The pay of these officers varies from £50 to £150.

Full prospectuses, lists of special lectures, and other particulars can be obtained on application to the Dean at the School.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.

The head quarters of this post-graduate school are situated at the Prince of Wales's General Hospital, which is in the midst of a densely populated North London district containing about a quarter of a million inhabitants. It contains 125 beds, and its precise situation is South Tottenham, N., where it is within a few minutes' walk of South Tottenham Station on the Midland Railway, Seven Sisters Station on the Great Eastern Railway, and Tottenham Hale on the Great Eastern main line. It is also readily accessible from Finsbury Park and Hackney by electric tram passing the hospital door, and by corresponding means may be reached easily from Dalston, Edmonton, and other parts of North London.

The college is recognized by the Admiralty and the India Office for the purposes of study leave, and by the University of London as a place for advanced study for the M.D. and M.S. degrees; the course of practical teaching of bacteriology is approved by the University of Cambridge for its D.P.H. diploma, and there are ample arrangements for the convenience of men who are thus working, or who, being in active practice, are desirous of getting themselves into touch with modern methods. There is provided for their use a reading and writing room, and they can obtain afternoon tea and receive telephonic messages; similarly there is a reference and lending library for their benefit, and a museum and pathological laboratory in which they can work. The hospital as a whole affords excellent facilities to qualified medical practitioners who wish to take part for a time in the work of an active general hospital, or to obtain special instruction in the several branches of medicine and surgery, since it is open to them to study diseases of the eye, ear, throat, nose, skin, fevers, children's diseases, psychological medicine, dental surgery, radiography, the application of electricity in disease, and the administration of anaesthetics. Throughout the sessions in which the year's work is divided, clinics, lectures, and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out-patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week except Saturday. Special classes are arranged in modern methods of the investigation and treatment of diseases of the lungs and heart, gynaecology, diseases of children; diseases of the throat, nose, and ear; diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, diseases of the skin, abdominal surgery, surgical anatomy, surgery of the urogenital tract, skiagraphy, anaesthetics, bacteriology, clinical pathology, vaccine therapy, pathological chemistry, and medical electricity. In all these classes the numbers are carefully limited, so as to give every member full opportunity for work.

As for fees, these are as follows: One guinea for a three months' course of study in any one department, which may be begun at any time; a fee of 3 guineas admits to the whole practice of the hospital for a similar term (one month, 2 guineas), and a perpetual ticket for the practice of the hospital may be obtained on payment of a fee of 10 guineas.

Additional information about the college and its work can be obtained on application to the Dean of the Post-Graduate College, at the hospital, or at 19A, Cavendish Square, London, W.1. It should, however, be stated that, owing to the war, the number of lectures and set demonstrations has of necessity been reduced.

TROPICAL MEDICINE.

THERE are Schools of Tropical Medicine in London and Liverpool, and several examining bodies have instituted diplomas or degrees in the subject. The Colonial Office now expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed, and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees follows.

DIPLOMAS AND DEGREES.

LONDON UNIVERSITY.—Tropical medicine is one of the six branches in which the M.D. degree may be obtained,

the regulations relating to the curriculum and examination corresponding to those applying to the other branches.

LONDON CONJOINT BOARD.—This body grants a diploma in tropical medicine to candidates after an examination usually held in the months of April and July. Ordinary candidates must present evidence of having attended, subsequently to obtaining a registrable qualification in medicine, surgery, and midwifery, (1) practical instruction in bacteriology, parasitology, medical zoology, and haematology, in a laboratory recognized for this purpose during not less than six months; (2) instruction in hygiene applicable to tropical countries; (3) the clinical practice of a hospital recognized for the study of tropical diseases during not less than six months. These conditions may be modified in the case of candidates who have had practical experience in tropical countries deemed likely to have furnished them with the same kind of training. The fee for admission to the examination is £9 9s. No further examination will be held until the termination of the war.

UNIVERSITY OF EDINBURGH.—This university grants a diploma in tropical medicine and hygiene after an examination which is usually held twice a year. It is open to those who are graduates of the university in medicine and surgery, and to registered practitioners who have had experience of tropical diseases in a tropical country, who may be approved by the Senatus on the recommendation of the Faculty of Medicine. In addition to this the candidates must show that they have attended approved courses of instruction in practical bacteriology (including the pathogenic micro-organisms of tropical diseases), in diseases of tropical climates (including the zoological characters and life-history of disease-carrying insects), in tropical hygiene, and in clinical study of tropical diseases. They must possess, too, certificates of efficiency in the conduct of *post-mortem* examinations. The examination is in the four subjects indicated, the fee being £4 4s.

UNIVERSITY OF LIVERPOOL.—A diploma in tropical medicine is given by this university to students who have been through the courses provided by the Liverpool School of Tropical Medicine, and have passed the examination held twice yearly by the university examiners. The examination lasts three days, and consists (1) of three papers dealing with tropical medicine, tropical pathology, and tropical sanitation and entomology respectively; (2) of a clinical examination; and (3) of an oral examination. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool.

UNIVERSITY OF CAMBRIDGE.—This university grants a diploma in tropical medicine and hygiene to any person whose name has been on the *Medical Register* for not less than a year provided that he passes the examination of the university in this subject. Previous to admission to the examination he must produce approved evidence that he has studied pathology (including parasitology and bacteriology in relation to tropical diseases), clinical medicine, and surgery, at a hospital for tropical diseases, and hygiene and methods of sanitation applicable to tropical climates.

The examination deals with the following subjects:

1. The methods of pathological and bacteriological investigation. The examination of the blood. The characters, diagnosis, and life-history of animal and vegetable parasites. The examination, chemical and microscopic, of poisonous or contaminated foods and waters.
2. The origin, pathology, propagation, distribution, prevention, symptoms, diagnosis, and treatment of the epidemic, endemic, and other diseases of tropical climates, including malaria, blackwater fever, trypanosomiasis, relapsing fever, dengue, yellow fever, plague, tetanus, beri-beri, dysentery and hepatic abscess, cholera, enteric fever, Malta fever, and specific diarrhoeal affections of the tropics; diseases due to cestode and other worms; filariasis, bilharzial disease; specific boils, sores, and other cutaneous affections; mycetoma, ophthalmic affections of the tropics, affections caused by poisonous plants and animals, and by poisoned weapons; sunstroke.
3. The general effects on health in the tropics of seasons and climate, soil, water, and food. Personal hygiene, acclimatization. Principles of general hygiene, with special reference to food supplies and water supplies, sites, dwellings, drainage, and the disposal of refuse. The sanitation of native quarters, camps, plantations, factories, hospitals, asylums, gaols, pilgrim and coolie ships. Principles and methods of disinfection.

Examinations are held in January and August each year, and last four days. The fee for the examination and

diploma is 9 guineas on admission or readmission. Application for further information should be made to Dr. G. S. Graham-Smith, Pathological Laboratory, Cambridge.

SCHOOLS.

LONDON SCHOOL OF TROPICAL MEDICINE.—This school is under the auspices of the Seamen's Hospital Society. Its buildings, laboratories, museum, library, etc., are within the grounds of the Branch Hospital, Royal Victoria and Albert Dock (Station, Connaught Road, Great Eastern Railway), and excellent opportunities are afforded to students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. In the hospitals of the society are to be found cases of tropical disease such as may be met with in actual practice in the tropics. There are three courses in the year, each lasting three months, beginning October 1st, January 15th, and May 1st respectively. The course is so arranged as to equip men for the Cambridge and English Conjoint Board diplomas in tropical medicine. A prospectus and other information can be obtained on application to the Dean, London School of Tropical Medicine, India Office, Whitehall, London.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—This school is affiliated with the University of Liverpool and the Royal Infirmary of Liverpool. Two full courses of instruction are given every year, commencing on January 6th and September 15th, lasting for the term of about thirteen weeks, and followed by the examination for the diploma of tropical medicine given by the University of Liverpool. Each course consists:

(1) Of a systematic series of lectures on tropical medicine and sanitation delivered by the Professor of Tropical Medicine at the university; (2) of systematic lectures and demonstrations on tropical pathology, parasitology, and bacteriology by the Professor of Parasitology and the Lecturer on Parasitology at the university; (3) of similar instruction on medical entomology by the Professor of Medical Entomology and the Lecturer on Entomology at the university; and (4) of clinical lectures and demonstrations delivered at the Royal Infirmary by the professor.

The instruction given occupies six hours a day for five days a week during the term. Teaching under headings (2) and (3) above is delivered in the laboratory of the school at the university, which contains accommodation for thirty students, with all necessary appurtenances, including a well-equipped museum, a class library, and access to the general departmental library. Teaching under heading (4) is given in the tropical ward and the attached clinical laboratories of the Royal Infirmary and the Royal Southern Hospitals on two or three afternoons a week.

In addition to the full courses, an advanced course of practical instruction in tropical pathology and medical entomology, lasting one month, is given every year in June; it is of such a kind as to be very useful to medical men returning from the tropics on short leave. A special course of instruction in entomology, etc., is also given three times a year to officers of the East and West African Colonial Services.

Students of the school who do not care to undertake the examination held by the university at the end of each term for its diplomas in tropical medicine are given a certificate for attendance if the latter has been satisfactory.

It is proposed to institute at an early date a course of instruction in tropical sanitation. Full particulars will be issued as soon as possible.

The new laboratories of the school adjoining the university, which are now completed, have been taken over temporarily by the War Office authorities as a hospital.

Since it was instituted the school has dispatched to the tropics thirty-three scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in twenty-one special memoirs, with many plates and figures, besides textbooks and numerous articles in the scientific press, also in the "Annals of Tropical Medicine and Parasitology" of the school.

Fees.—The fee for the full course of instruction is £13 13s., with an extra charge of 10s. 6d. for the use of a microscope if required. The fee for the Diploma Examination is £5 5s., and that for the Advanced Course is

£4 4s. Further information about the school may be obtained on application to the Secretary, 10B, Exchange Buildings, Liverpool.

PSYCHOLOGICAL MEDICINE.

THE study of mental diseases has long been a necessary part of the ordinary medical curriculum, and mental psychology is one of the branches of medicine which candidates for the M.D. degree of the University of London can take up. In addition diplomas in psychiatry or psychological medicine can be obtained from the universities of Cambridge, Edinburgh, Leeds, and Manchester. The Medico-Psychological Association of Great Britain and Ireland also grants certificates of proficiency after examination and encourage study of psychology and connected subjects by the offer of prizes for competition.

Those who take up psychological medicine as a career work as medical officers either of private mental hospitals, or of county or other public institutions of the same order. In all cases they are resident officers, those in the lower ranks always receiving board and lodging in addition to their salary. As a whole, they fall into three ranks—junior assistant medical officers, senior assistant medical officers, and medical superintendents. The salaries of those belonging to the junior rank have hitherto been in the neighbourhood of £150 a year, and those of senior assistants about £300 a year, but have recently shown some tendency to rise. Medical superintendents, whose pay commonly ranges between £500 and £1,500 a year, are always provided with a house in the grounds of their asylum, and usually draw various allowances.

However, asylum work as a career is by no means growing in favour, and is unlikely to do so until all the public asylums throughout the country have been linked up in such fashion that their officers can be regarded as members of one common service. At present it is quite possible for a man who does excellent work to remain in the lower rank all his life, and this fact, coupled with the desirability of minimizing as far as possible other existing drawbacks to asylum life, has led to the starting of a movement for reform; and in this the British Medical Association is co-operating.

PUBLIC HEALTH SERVICES.

THE Public Health Service, to use the term in a strict sense, consists of medical officers of health appointed by local public health authorities and holding office under varying conditions of tenure. In addition, there are county medical officers appointed by the county councils. The latter are not, strictly speaking, public health authorities; the duties of their medical officers are somewhat similar to those of other medical officers of health, but include few executive functions. In many of the county boroughs and counties, assistant medical officers of health or assistant county medical officers are appointed, and such appointments may afford stepping stones for promotion to higher offices. The service is, however, not unified throughout the country, and there is no regular system of promotion; appointments are to be obtained only by application to some particular local authority which has advertised a vacancy.

Also ungraded are two other services which have been brought into existence by recent legislation, and whose members are charged with duties which bring them into more or less direct relation with public health authorities or county councils and their officers. The members of the one are called school medical officers, and those of the other tuberculosis officers. Appointments as school medical officer are made by education authorities, while appointments as tuberculosis officer are made in fulfilment of the duties imposed directly on the county councils and the county borough councils, and indirectly on the Insurance Committees by the scheme for the treatment and prevention of tuberculosis which was worked out by the Local Government Board for England in consultation with the Insurance Commissioners.

The Local Government Board for England, it may be noted, employs a staff of medical inspectors in connexion with the performance of its duty as the controlling depart-

ment of the Government in matters of public health, and the same is true of the corresponding boards in Scotland and Ireland. The medical men forming these staffs are, however, appointed to their position directly by the head of the Local Government Board in each country, and the posts are not open to public competition.

MEDICAL OFFICERS OF HEALTH.

The office of medical officer of health in a county borough—a designation which now includes nearly all the larger towns—is in practice a permanent appointment so long as the incumbent desires to retain it, and is the same by law in administrative counties and metropolitan boroughs. The position of a medical officer of health to an urban or a rural district, or to a combination of districts which have joined together to obtain the services of a whole-time medical officer of health, is much less satisfactory, for his appointment is terminable at the will of the public health authority served by him. This fact tends to militate against the efficiency of the service, and consequently the British Medical Association, in co-operation with some other bodies, has long been endeavouring to induce Parliament to establish security of tenure of office and superannuation for medical officers of health. In view of statements recently made by the Government, security of tenure, at any rate, seems likely soon to be granted. A medical officer of health to a district or combination of districts having 50,000 inhabitants must hold a diploma in public health. The first step which must be taken by any medical man who desires to follow the career of medical officer of health must be therefore to obtain such a diploma.

SCHOOL MEDICAL OFFICERS.

School medical officers are appointed by local education authorities under schemes of medical inspection of school children which must be approved by the Board of Education. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard the education of such children, and to inform their parents of its existence. But practically their duties vary considerably in different areas. This is because most approved schemes of inspection include systems of work which aim at facilitating the task of parents in obtaining for their children the necessary treatment, at checking the results of the latter, and at keeping each defective child under skilled observation both at home and at school until it has passed altogether out of the education authority's hands. The general object of all schemes alike is to make the inspection imposed by law of benefit not merely to the individual child, but to the community at large, by preventing conditions which lead to the existence of a large proportion of inefficient citizens among the adult population. In short, the work is so far related to that of a medical officer of health that in most areas the senior school medical officer fills both appointments, his work, when necessary, being supplemented by that of whole or part-time assistants. Whole-time assistants are commonly paid salaries ranging between £250 and £300 a year, the chief attraction of the posts being that they may lead on to appointment as medical officer of health of some large area where the combined salary of medical officer of health and school medical officer will represent a fair income. In view of this consideration, if for no other reason, it is desirable for a prospective whole-time school medical officer to obtain a diploma in public health.

TUBERCULOSIS OFFICERS.

The prescribed duties of tuberculosis officers are to act as advisers to Insurance Committees in connexion with the operation of the sanatorium clauses of the National Insurance Act and to take charge of the work of the tuberculosis dispensary, which is the main unit of the Departmental Committee's scheme. A tuberculosis officer is a whole-time officer; he should have special training in tuberculosis work, and be of suitable age and attainments to command general confidence. At present the number of appointments is small, and the salary generally attached to them is in the neighbourhood of £500 a year.

SANITARY SCIENCE.

In June, 1917, the University of Cambridge issued regulations for the Examinations in Sanitary Science,

conducted by the State Medical Syndicate of the University. Two examinations will be held during the year 1918—one in April and one in October. Any person possessing a registered qualification in medicine, surgery, and midwifery may be a candidate, provided that he has satisfied certain demands laid down in the regulations. The examination will consist of two parts, the first having reference to the general principles of sanitary science, the second to State medicine and the applications of pathology and sanitary science. All applications for information respecting these examinations should be addressed to Mr. J. E. Purvis, M.A., The Chemical Laboratory, Pembroke Street, Cambridge.

DIPLOMAS IN PUBLIC HEALTH.

Most of the universities and licensing corporations now grant diplomas in public health to candidates who pass the examinations imposed by them. Since all such tests must conform to the requirements of the General Medical Council, there is considerable similarity in their nature, though they differ not a little in their reputed difficulty. All of them aim at excluding any candidate who does not appear to have a thorough knowledge of his work in theory and in practice, for the regulations of the General Medical Council demand that the granting of a diploma in Sanitary Science, State Medicine, or Public Health shall be proof of the "possession of a distinctly high proficiency, scientific and practical, in all the branches of study which concern the public health." The tests, in short, are supposed to constitute an honour and not a mere pass examination. As regards the special tuition required, it is now easy to obtain this in practically every centre of medical education, and at almost every medical school of any importance. It is desirable to note in this connexion that the chemical and bacteriological examinations for many of the health diplomas are so practical, and the time allowed so short, that unless a candidate—even though familiar with the duties of M.O.H.—has a considerable amount of the manipulative dexterity only to be acquired by ample work in a laboratory, he would not be likely to satisfy the examiners.

The regulations of the General Medical Council require that every candidate (subsequent to obtaining a registrable qualification in medicine and surgery) shall have passed through a stated curriculum in the subjects of sanitary science. This must last not less than nine calendar months, and include four months' study in a laboratory in which chemistry, bacteriology, and the pathology of diseases of animals transmissible to man are taught, six months' practice study of the duties involved by public health administration, and attendance at least twice weekly for three months on the practice of a hospital for infectious diseases, at which instruction is given in methods of administration. These rules do not apply to practitioners registered or entitled to be registered before January 1st, 1890, while that regarding six months' practical study of public health administration is waived in the case of a candidate who has himself been in charge of a sanitary district with a population of not less than 15,000 for a period of not less than three years. The study in question must be passed under the personal supervision of a medical officer possessing certain definite facilities for affording it, these being carefully described in the regulations. The period may be reduced to three months in the case of a candidate who has undergone a corresponding period of study in the public health department of a recognized medical school, or who has been resident medical officer at a hospital for infectious diseases with accommodation for 100 patients for not less than three months. The laboratory study must include at least 240 hours' work, not more than half being devoted to practical chemistry. The examinations imposed by the diploma-granting bodies must extend over not less than four days, one at least being devoted to practical work in the laboratory, and one to practical examination in, and reporting on, subjects within the duties of a medical officer of health, including those of a school medical officer.

The steps which examining bodies take to ascertain the candidate's fitness for a diploma are in all cases much the same, though the order in which the subjects are taken is not always identical. Every candidate, therefore, should when he has settled what diploma or degree in State medicine he wishes to obtain, seek the schedule relating

to it from the authority concerned. A certain number of the universities grant degrees in the subject as well as diplomas, but only the latter constitute a legal qualification in State medicine.

THE PUBLIC SERVICES.

THE ROYAL NAVY, THE ARMY, AND THE INDIAN MEDICAL SERVICE.

THE medical departments of the Royal Navy, the Army, and the Indian Government normally employ between them some three thousand medical men, and fill vacancies in the ranks of the services thus formed by offering commissions for competition once or more often each year. All candidates must be between the ages of 21 and 28 years, and besides possessing registrable qualifications to practise medicine and surgery in Great Britain and Ireland must be adjudged by the Medical Boards appointed for the purpose to be physically fit for service before permission is accorded them to compete at the entrance examinations. Special attention is given to a candidate's power of vision; a moderate degree of myopia is not considered a disqualification, provided that it can be corrected by glasses so as to secure adequate vision for the performance of operations, and that no organic disease of the eye exists. Testimony has also to be furnished, or is sought by the authority concerned, with regard to the candidate's moral and general character, and the Secretary of State in each service reserves the right to refuse permission to compete to any candidate he pleases.

In the case of a candidate for the Indian Medical Service, the certificates submitted must include one showing that he has studied in an ophthalmic department for not less than three months, the work including refraction, and candidates for the other two services who have qualified in the Officers' Training Corps, or who have been employed on active service, receive an allowance of marks. In all three services the prospect of a medical officer attaining to the highest administrative grades depends to a large extent on the regulations with regard to compulsory retirement at the age of 55 (if below a certain grade at that age), so there is a distinct advantage in entering them at the earliest possible age.

In peace and apart from climatic conditions the lives of officers in these three services are of a less trying nature than those of civilian practitioners, and in the Royal Army Medical Corps, and still more in the Indian Medical Service, the opportunities for professional work of the highest kind are exceptionally great. In regard to emoluments, the pay in no rank is high, but in all it is sufficiently good to make the possession of private means not absolutely necessary. An officer in the Indian Medical Service, for instance, can retire after seventeen years' service on £300 a year, and after thirty on £700 a year with large additions should he have been employed in certain positions. In the other two services twenty years is the lowest pensionable length of service (the minimum is £365 a year, the maximum £1,125); but from either of them an officer whose record is good can retire while still under 30 years of age, with a gratuity of £1,000. In the Indian Medical Service, after working for three years in a military capacity, officers are allowed as a rule to transfer, if they please, to the civil department. Therein they do work not essentially dissimilar from that performed by civilian practitioners in other warm climates, but retain their military titles and are promoted from one grade to another as their service lengthens. It should be added that for several years previous to the war competition for admission to the Navy was very slight, while that for admission to the Indian Medical Service had greatly fallen. The reason is that the attractions of both services set forth above are to some extent counterbalanced by removable causes of discontent among their members. The nature of these has been indicated from time to time in the BRITISH MEDICAL JOURNAL.

Candidates for all three services have to fill in printed forms before the question of permitting them to compete is considered, and copies of these, together with detailed information as to what each service has to offer, can be

obtained on application to the Director-General of the Royal Navy, the Secretary of the War Office, and the Military Secretary of the India Office, respectively.

PRISON MEDICAL SERVICE.

CANDIDATES for the medical staff are approved by the Secretary of State for the Home Office on the recommendation of the Prison Commissioners. The Chairman of the Board is Sir Evelyn Ruggles-Brise, K.C.B. Application for employment may be made to the Board on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W.1.

In the smaller prisons the medical officer is usually a local practitioner, but in the larger the members of the medical staff are required to devote their whole time to the service.

In the case of those required to give their whole time to the service the appointment in the first instance is to the post of deputy medical officer, and from the seniors of this rank the medical officers are selected as vacancies occur. The deputy medical officers are paid £225 yearly, rising to £400, with unfurnished quarters. The whole-time medical officers are paid £450, rising to £550, with unfurnished quarters. There are twenty deputy medical officers, and nine whole-time and thirty-eight part-time medical officers. The number of vacancies is never large.

APPOINTMENTS UNDER THE COLONIAL OFFICE.

MEDICAL appointments are from time to time filled up by the Colonial Office in various Crown and other Colonies, and vacancies in the West African Medical Staff are of fairly frequent occurrence. As a rule, officers are required on appointment to undergo a three months' course of instruction at the London or Liverpool School of Tropical Medicine, and to obtain a certificate of proficiency before taking up their appointment. In addition to the ordinary medical appointments, vacancies also occasionally occur for which specialists are required—for example, to take charge of a lunatic asylum.

The nominal value of the appointments varies very considerably; but, as a general rule, it will be found on close examination that the rates of pay correspond in real value pretty closely when questions of climate, opportunities for private practice, the cost of living, and the actual work demanded are taken into consideration. The posts to which the lower salaries are attached commonly involve work which can be regarded as merely an adjunct to ordinary private practice, while high pay means either few opportunities for practice, an undesirable climate, or work of a special character demanding high administrative ability. Taken as a whole, all these appointments may be put down as offering their occupant the opportunity of gaining his livelihood, and possibly saving a little money, in a fashion which will test his abilities to the full. Pamphlets relating to the various appointments in its gift are published by the Colonial Office, and copies can be obtained on application by letter to the Assistant Private Secretary, the Colonial Office, Downing Street, S.W.1.

It may be added that, apart from the Government appointments mentioned, a large number of men find employment as medical officers of mining and other companies carrying on their operations in various parts of the tropics. Much caution should be exercised in accepting these appointments, and those to whom they are offered would find it worth while to read what was said on the subject in our issues for May 25th and August 24th, 1912.

Considerable increases have been made since 1914 in the salaries and allowances attaching to posts in the different grades of the West African Medical Staff. These improvements will, it is hoped, render these posts more attractive to the young and well-qualified medical men for whom they are intended. As a result of the war, however, the Colonial Office has found it very difficult to obtain the services of medical men for any of the Colonies and Protectorates to which medical officers are appointed from this country.

MEDICAL MISSIONARIES.

To medical men suitably endowed the mission field seems to offer increasing opportunities for interesting work. Just before the war, over 450 medical practitioners holding British degrees or diplomas were employed in different parts of the world by missionary societies, and the latter seem to stand in constant need of men and women to fill vacancies as they occur, and also to enable them to take advantage of fresh openings. It is not usually expected or desired that a medical missionary should take a position such as would otherwise be occupied by an ordained clergyman or minister. But it is essential that he should be prepared to take his share of definite missionary work in any hospital in which he may be placed. As for scientific and other qualifications for the work, a medical missionary, apart from being physically capable of sustaining what may prove to be a trying life, should be a thoroughly well trained physician and surgeon. It is very desirable that he should have held a resident appointment at a general hospital and have a good knowledge more particularly of practical surgery, tropical medicine, and the treatment of eye diseases. Societies from whom useful information can be obtained are the London Medical Missionary Association, 49, Highbury New Park, N.5.; the Edinburgh Medical Missionary Association, 56, George Square, Edinburgh; and the Society for Promoting Christian Knowledge, Northumberland Avenue, W.C.2.

MEDICAL PRACTICE IN BRITISH COLONIES AND FOREIGN COUNTRIES.

MEDICAL Acts have now been passed in almost all places forming part of the British Empire beyond the seas, and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are always admissible merely on payment of a fee, provided they produce evidence that they are of good repute and eligible for registration in the United Kingdom. The only exception to this statement that need be made relates to the Dominion of Canada. Until quite recently each of its provinces acted in medical connexions as an independent State, but in 1913 a Medical Act which established a State examination and a common register for the whole country came partly into operation. It could not come into complete operation until each province had amended its existing Medical Act so as to come into line with the new Act. This step is understood to have now been taken by all of them; but it is not clear how far the reciprocity with the United Kingdom previously accorded by all but Ontario and the three Western provinces has been affected. Consequently, any medical man proposing to practise in Canada should first communicate with the Registrar of the Medical Council of Canada, 180, Cooper Street, Ottawa, stating what degrees or diplomas he holds and the length of the curriculum he has undergone, and asking for information as to the precise steps he must take in order to obtain admission to the Dominion Register.

Italy, Egypt, and the Principality of Monaco are the only foreign States which accord a right to practise in virtue of British degrees and diplomas, though the authorities in Spain occasionally issue a temporary permit in favour of British practitioners, and those of Holland and Greece sometimes exempt British practitioners from portions of the examinations imposed on ordinary candidates for registration. In all other Continental countries a British medical man desiring to exercise his profession therein must pass practically the same examinations as those imposed on natives of the country. The same observation applies to all foreign States in the South American continent, while each of the United States of North America has its own laws and regulations; some of them admit any holder of a degree or diploma to their Register, but the majority require a candidate for registration to submit to an examination.

Dental Surgery.

THE profession of dentistry in this country is on the same footing as that of medicine; that is to say, only those who have complied with certain stipulations laid down by the

General Medical Council have a legal right to practise dental surgery. This, unfortunately, by no means implies that the practice of dentistry is confined to legally qualified practitioners, for the Dental Acts offer even less protection to dental surgeons than do the Medical Acts to doctors. An ordinary medical man is within his legal rights if he practises dental surgery, but since owing to his lack of the necessary technical training he could not do so with success, dental surgery is in effect legally practised solely by men of two classes—those who hold a qualification both in dental surgery and in medicine and those who hold a qualification in dental surgery alone or have otherwise obtained admission to the *Dentists Register*. The early stages of the education of dental and medical students cover the same subjects, and it is both possible and advisable to combine the two educations.

In any case a prospective dental surgeon must obtain registration as a dental student (see p. 311) and thereafter pursue a curriculum which lasts a minimum of four years.

During the last two years, which must be spent at a medical school and hospital, concurrently with attendance at the dental hospital, in addition to studying anatomy and physiology, surgery and pathology, he will include in his work the more specific subjects—namely, dental anatomy and physiology, dental histology, dental surgery and pathology, and practical dental surgery, for all of which he must be "signed up" before entrance to the Final Examination for the Licence.

Recognized dental schools are numerous: in London there are those connected with the Royal Dental Hospital, Leicester Square; the National Dental Hospital, Great Portland Street; Guy's Hospital, and the London Hospital. In the Provinces and Scotland and Ireland there are those connected with the universities of Sheffield, Manchester, Liverpool, Leeds, Bristol, Durham, and Birmingham, and the Devon and Exeter Dental Hospital; the Edinburgh Incorporated Dental Hospital; the Glasgow Incorporated Dental Hospital; the Royal Infirmary, Glasgow; and the Dental Hospital of Ireland, Dublin. As for qualifications in dental surgery, these are almost equally numerous. There are considerable variations in the order in which different licensing bodies require various subjects to be taken up, and every prospective dental student should consequently study not only the regulations of the General Medical Council, but also those of the body whose licence or degree he hopes to obtain.

ORDER OF THE BRITISH EMPIRE.

IN our notice last week of those medical men and women whose names appeared in the first list of the new Order of the British Empire, Dr. Duncan McFadyen Millar and Dr. William Ernest Nelson should have been included among the Officers of the Order.

THE Right Hon. Christopher Addison, M.D., M.P., was on August 31st sworn Minister of Reconstruction.

THE Royal Sanitary Institute will hold a meeting on Saturday, September 29th, at 10.30 a.m., at the Town Hall, Chatham. Surgeon A. G. L. Reade, R.N.V.R., will open a discussion on epidemic cerebro-spinal meningitis. Dr. J. Holroyde will speak on the housing problem and Mr. R. L. Honey on public abattoirs; discussions will follow.

A COURSE of elementary lectures on infant care for teachers, infant welfare workers, and mothers, will be held under the auspices of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy, on Mondays, at 5.30 p.m., from October 1st to December 17th, at 1, Wimpole Street.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

INFECTIVE JAUNDICE.

BY

SIR BERTRAND DAWSON, K.C.V.O., C.B., M.D.,
B.Sc., F.R.C.P.,COLONEL A.M.S.; PHYSICIAN TO H.M. THE KING; CONSULTING
PHYSICIAN, BRITISH EXPEDITIONARY FORCE; PHYSICIAN
LONDON HOSPITAL;

W. E. HUME, M.A., M.D. CANTAB., F.R.C.P. LOND.,

LIEUT.-COLONEL R.A.M.C.(T.F.);

AND

S. P. BEDSON, M.D., M.Sc.,

CAPTAIN R.A.M.C.

HISTORICAL ACCOUNT.

EPIDEMICS of jaundice have been described from the earliest times, and many of the best accounts have been compiled from the study of the disease in armies in the field. Cockayne draws attention to the fact that the author—probably Hippocrates—of the *De Internis Affectionibus* describes "ἄλλος ἵκτερος. ἐπιδήμιος οὗτος καλέεται, διότι πᾶσαν ὥρην ἐπιδραμβάνει. In 1745 Clegghorn described an outbreak of epidemic jaundice in Minorca, and Larrey, in 1800, published an account of an epidemic of jaundice during the siege of Cairo, and drew particular attention to the contagiousness of the disease and to the occurrence of haemorrhages in his patients. Amongst French writers, Ozanam (1846-9), Monneret (1859), the elder Laveran (1865), Lancereaux (1882), Landouzy (1882), and Mathieu (1886), have all described epidemic diseases of varying intensity in which jaundice was a constant feature. Lancereaux described his cases under the title of "Ictère grave essentiel," and Landouzy called the disease "Fièvre bilieuse," and Mathieu, drawing attention to the frequent occurrence of relapses, gave to his description the title of "Ictère fébrile à rechutes." The accounts of the diseases described by these authors vary, and it is probable that there were different etiological factors in each epidemic.

Attention may be drawn, however, to certain descriptions in so far as they throw light upon the particular type of epidemic jaundice which is to be described in these pages. In 1859 Carville described an epidemic in the garrison at Gaillon, and gives an account of 47 cases, of whom 11 died. All developed jaundice, and albuminuria was present in every case. Haemorrhages were common; 15 had epistaxis, in 3 there was purpura, and in one haematemesis. The incubation period was six days. A similar epidemic was described by Worms in St. Cloud in May, 1865.

Mathieu in 1886 described cases of jaundice and drew attention to the fact that the term "catarrhal jaundice" was an insufficient description, and claimed that the fever, general symptoms, enlargement of the spleen and albuminuria, justified the title of infectious jaundice.

Weil in 1886, and some months after the publication of Mathieu's report, described four cases of infectious jaundice, and drew attention to the relapses of fever which occurred in two out of the four cases. From this time onwards the symptom-complex of fever, jaundice, enlargement of the liver and spleen, the occurrence of haemorrhages, and occasional febrile relapses, have been described under the name of Weil's disease. This last title has served the purpose of labelling with a simple name any disease which embraced the signs and symptoms which we have just enumerated. Both historically and scientifically the title is incorrect and vague. Epidemic jaundice was described by the Father of Medicine, and his disciples in later years have only added little by little to a clinical picture which is still far from being complete. There is no doubt that there are many and different etiological factors which can give rise to a clinical picture in which fever, jaundice, haemorrhages, enlargement of the liver and spleen, and relapses of fever are variously, but not constantly, present. In none of the descriptions quoted above is the picture complete. In none has the cause ever been proved, and in many it is not even suggested. Using the last three years, however, we have been enabled to recognize a form of infectious jaundice in which the clinical and pathological picture is uniform and constant, and of which the cause has been discovered and proved.

In November, 1914, two Japanese workers, Inada and Ido, showed the presence of a spirochaete in the liver of a guinea-pig which had been inoculated with the blood of a patient suffering from a form of infectious jaundice. Some months later they proved the specificity of this

spirochaete, and gave to it the name of *Spirochaeta ictero-haemorrhagiae*. In a later part of this paper the work of these Japanese authors is set forth in greater detail. In the British and French armies it has been shown conclusively that an infectious disease usually accompanied by jaundice is caused by the *Spirochaeta ictero-haemorrhagiae*, and descriptions of the clinical and pathological findings have been published by Dawson and Hume, Stokes, Ryall, and others in the British army; and in the French army by Martin and Pettit, Garnier and Reilly, and Costa and Troisier.

Before describing this disease it may be recalled that jaundice has been a relatively common disorder in armies in the field. In the Federal troops in the war between North and South America there were 22,509 cases, with 161 deaths, amongst a total of 2,218,559 men. In 1870, from February to May, there were 799 cases amongst 33,380 men in the Bavarian troops stationed to the south-west of Paris. During five months in the South African war there were 5,648 cases, with a small mortality.

Since the commencement of the present war we have been unable to ascertain the incidence of cases of jaundice amongst the British and French troops in France. Before we were in possession of the Japanese work we were able to prove that certain cases of jaundice belonged to the enteric group of diseases. In the summer and autumn of 1915 our attention was arrested by the occurrence of severe cases of jaundice in which there were high fever, haemorrhages, enlargement of the liver, and a tendency to febrile relapses, which in no way conformed either clinically or bacteriologically to the typhoid group.

In the autumn of 1915 we made a special endeavour to study these cases by collecting them into a single hospital, and the result of our work has been published in detail in the *Quarterly Journal of Medicine*, October, 1916, and January, 1917. It was only in April and May, 1917, that we were able to show that the *Spirochaeta ictero-haemorrhagiae* was the cause of this disease, after we had read the account of the Japanese work published in the *Journal of Experimental Medicine*.

CLINICAL DESCRIPTION OF THE DISEASE.

In order to draw attention to the characteristic features of this disease, a complete case will be briefly described and an account of the chief signs and symptoms will be set forth under the headings of the various systems of the body.

On August 7th, 1917, Pte. A. B. was suddenly seized with vomiting and diarrhoea, with a feeling of intense weakness. For two days he lay in his billet with a temperature of 103° to 104° and had frequent diarrhoeal stools. On August 9th the prostration was very marked and there was a considerable amount of blood in the stools. The temperature was 101°. On August 12th he was noticed to be jaundiced. On August 14th he had an attack of haemoptysis and spat up about one pint of blood, and the expectoration was blood-stained for the following five days.

On admission to a base hospital on August 16th, there was universal intense jaundice and the temperature was 101.2°. There was a scabby mass of haemorrhagic herpes about the lips. The tongue was brown and very dry. The patient was drowsy and there was considerable abdominal distension and discomfort. The initial diarrhoea was followed by constipation, which necessitated the use of enemata. There was marked tenderness in the right hypochondrium and the liver was enlarged to three fingerbreadths below the right costal margin. The spleen was not palpable. The red blood cells numbered 4,800,000 to the cubic millimetre and the haemoglobin was 80 per cent. The white cells numbered 24,000 to the cubic millimetre and a differential count showed:

Polymorphonuclear leucocytes	82 per cent.
Lymphocytes	10 "
Large mononuclear leucocytes	5 "
Coarsely granular eosinophile leucocytes	3 "

The urine was loaded with bile, and there was a sixth of a boiled test tube of albumin together with granular casts. Some bile was escaping into the duodenum as the stools were of a light brown colour.

There were crepitations to be heard over the lower lobes of the lungs. There was no recurrence of haemoptysis or melaena. During the first fortnight of the illness the patient complained much of pains in the back and

limbs. On August 20th the temperature had fallen to 98° to 99°, though the jaundice was still intense. On August 26th the jaundice was rapidly fading, and on this day spirochaetes were found in the urine in large numbers. During the next five days the general condition of the patient improved so much that he was sent to England on August 31st. There was no secondary rise of fever while the patient was in France.

Such is the usual history of a case of moderate severity, and the noteworthy features are the following: A sudden onset with gastro-intestinal symptoms and high fever, the marked prostration, the occurrence of melaena and haemoptysis, the presence of haemorrhagic herpes, the appearance of jaundice on the fifth day, the fall of temperature at the end of eleven days, and the finding of typical spirochaetes in the urine.

GENERAL FEATURES OF THE DISEASE.

The Onset.—The patient has almost invariably been attacked by the disease either in the trenches or immediately after having left them. The onset is usually sudden, with shivering, pains in the head and particularly behind the eyes, generalized pains, and a feeling of extreme prostration. So sudden is the onset that the patient can frequently point to an exact moment when he finds himself overcome; as one said, he "fell out very weak" on the march; or in another instance, he "suddenly collapsed at church parade." At the time of reporting sick the temperature is raised to 103° to 105° and the pulse rate is about 100 per minute. During the first two or three days before the appearance of jaundice there are vomiting, great prostration and lassitude, with abdominal and muscular pains. The conjunctivae are injected, and herpes, which rapidly becomes haemorrhagic, appears on the lips.

Gastro-intestinal.—A dirty, brown tongue and anorexia is common to all; constipation is the rule, and it is only rarely that there is diarrhoea at the onset, as in the case described above. The constipation is usually extreme and has to be relieved by enemata. The stools may become clay-coloured, though in most cases the presence of a small quantity of bile gives the stool a light-brown coloration. Usually there is considerable abdominal tenderness, which is more marked in the upper than in the lower abdomen. Though vomiting is usual at the onset, it generally ceases before the patient reaches a base hospital, on the sixth to eighth day of the disease. Hiccough was occasionally present in very severe or fatal cases. Melaena sometimes occurred in patients with diarrhoea.

The liver is frequently enlarged to the extent of three fingers' to a hand's breadth below the right costal margin and the tissues covering it are usually very sensitive and tender.

The spleen has only been palpable on two occasions in our experience. From observation at operation and from the size of the organ at *post-mortem* examination it seems certain that the spleen is very rarely sufficiently enlarged to be palpable.

The superficial lymphatic glands are frequently palpable in the axillae and groins.

Haemorrhages.—Out of eighteen severe cases under our care, fourteen had haemorrhages. Haematemesis occurred in four and haemoptysis in six. Epistaxis was considerable in four cases and slight in two cases. Melaena was observed in three instances and in three there was a marked purpuric eruption in the skin. In one patient there were epistaxis, haemoptysis, and melaena.

The Skin.—The jaundice usually appears about the fourth day of disease and gradually deepens up to the eighth or ninth day and then fades. In some cases it is very intense and the skin takes the greenish hue met with in complete obstruction of the common bile duct. Herpes labialis, which is haemorrhagic, occurs in at least 40 per cent. of all cases. Pruritus is rarely intense, though patients frequently complain of some itching of the skin. The conjunctivae are often injected and the eyeballs are tender.

The Circulatory System.—The rate of the heart does not increase in proportion to the rise of temperature, and in severe cases with a temperature of 104° to 105° the pulse-rate may be only 100 per minute. The rhythm of the heart is not usually affected, except in one patient, in

whom auricular fibrillation, of which records were obtained, persisted for five days. The size and sounds of the heart are perfectly normal. The blood pressure never falls as it does in the enteric group of diseases, and the systolic pressure ranges about 120 mm. of mercury. The qualitative changes in the peripheral blood will be described in the section on clinical pathology.

The Respiratory System.—In all severe cases there are the evidences of an acute bronchitis, but we have never discovered any signs pointing to bronchopneumonia or lobar pneumonia. Reference has already been made to the occurrence of haemoptysis and rusty sputum. The respiratory rate may be increased to 28 or 30 per minute in severe cases, and in fatal cases the type of breathing is that met with in cases of cholaemia and uraemia.

The Nervous System.—Frontal headache and aching behind the eyeballs is a constant complaint, and is little relieved by antipyretics. The early weakness and prostration are very characteristic of this disease. In our fatal cases twitchings and convulsions preceded the coma in which the patients died. In many cases the muscular pains are very intense, and the whole body is so sensitive that the patient cannot bear any pressure upon it. One patient complained of xanthopsia.

The Urinary System.—Three of our patients had retention of urine, which required the use of the catheter for two or three days. The cause of this disability probably lay in the central nervous system. The urine usually contains a large quantity of bile, which sometimes gives it a dark porter colour. The bile does not usually disappear from the urine till the end of the fourth or fifth week. Albumin can nearly always be detected by the boiling method. In more severe cases, after heating in a test tube and allowing it to stand for twenty-four hours, the albuminous deposit amounts to one-sixth of the boiled test tube. Casts, hyaline and granular, are frequently found without centrifugalization, and at times free blood cells are seen in the deposit. The presence of reducing sugar was never detected, though acetone is said by others to occur in cholaemic cases, probably the result of starvation. The chemistry of the urine has been fully worked out in this disease by certain French authors, who lay considerable stress on the evidences of renal insufficiency.

The Fever.—The initial rise of temperature to 103° or 105° has already been noted, and during the first twelve or fourteen days there is an irregular range of temperature between 100° and 103°, which gradually falls by lysis to normal or subnormal. After the fall the temperature may be subnormal for two to three days. After this, in some cases about the beginning of the third week, there is a secondary rise of temperature, which lasts for ten to fifteen days. During this period of secondary fever there are usually no evidences of exacerbation of symptoms, and it is difficult to account for its occurrence. In those cases in whom there is no secondary fever the temperature

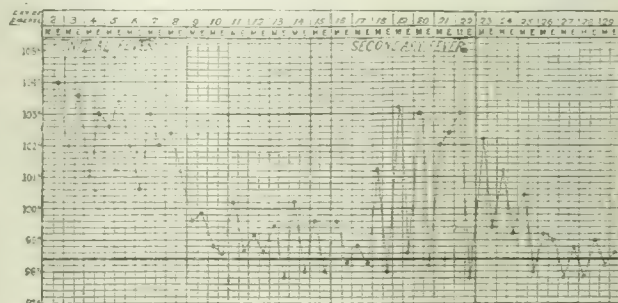

CHART I.

may swing about 99° for a week or more before finally settling to the normal. Chart 1 shows a characteristic fever of relapse.

Course of the Disease.—The first three or four days have been described in the section on the onset of the disease. The jaundice, which has appeared about the fourth day, gradually increases, and is most intense about the tenth to twelfth day. It is then that the temperature falls to normal. In uncomplicated cases the patient begins to improve and the jaundice begins to disappear at the end of the second week. Between the third and fourth weeks

FIG. 1.—Section of liver from a case of spirochaetal jaundice. The liver cells and their arrangement appear normal. It shows biliary stasis and collections of cells in the portal areas.

FIG. 2.—Section from the same liver as Fig. 1. (High power.)

FIG. 3.—Spirochaetes in the blood of a guinea-pig experimentally infected.

FIG. 4.—Section of liver from a case of spirochaetal jaundice. Showing dissociation of cells.

convalescence has become established. The whole disease is more protracted in severe cases, and convalescence may not begin until the end of the fourth week. As far as we know, the disease leaves behind it no untoward symptoms.

The following is an account of a fatal case:

Pte. C. D. was taken ill with a sudden chill and shivering on December 16th. He had to take to his bed, and complained of headache, nausea, and pains in both thighs. He frequently felt chilly and had pain in the epigastrium. On December 21st he became jaundiced. On this day no abnormal physical signs could be detected in any of the systems, except some epigastric tenderness, jaundice, and a haemorrhagic herpetic eruption on the lips. Vomiting had been occasional from the onset of the illness, and at the end of the first week nothing could be retained in the stomach. After the seventh day the jaundice steadily deepened and the urine was loaded with bile and contained one-sixth of a boiled test tube of albumin. The stools were liquid and of a pale yellow colour.

Except on the first day of admission to a base hospital (fourth day of disease), when the temperature was 101°, there was no pyrexia, and both the pulse and respiration rates fell, to 60 and 16 respectively. There was considerable tenderness of the upper abdomen and the muscles were slightly rigid. The liver was enlarged and the edge extended three fingerbreadths below the costal margin. The spleen was not palpable. An examination of the blood showed 34,100 white cells per cubic millimetre, and the differential count was:

Polymorphonuclear leucocytes	... 93 per cent.
Lymphocytes	... 6 "
Large mononuclear leucocytes	... 1 "

A culture made from the urine was sterile. The faeces showed some blood, but no parasites, no ova, and no organisms of the enteric group were detected.

In the forenoon of December 29th some twitching of the face and arms was noticed, and about an hour later the patient had a general tonic, followed by a clonic convulsion. The patient died one hour after this convulsion. The most noteworthy lesions at the *post-mortem* examination were subendocardial, subpleural, and subperitoneal haemorrhages and large extravasations of blood into both lungs, like infarcts.

PROGNOSIS.

Most cases recover fully, and we would estimate that the mortality is not more than 4 to 5 per cent.

TREATMENT.

Thus far the treatment has been purely symptomatic. During the febrile period the patient is encouraged to drink large quantities of fluid, and an alkaline mixture is usually exhibited. Constipation is combated either by saline purges or by enemata. Salvarsan has been tried, but it is of no avail. We believe that the serum of convalescent patients has been injected into the blood stream of severe cases, but the results of this method of treatment are not in our possession. An antiserum has been prepared and is available for use in the army.

DIFFERENTIAL DIAGNOSIS.

The rôle of the *Spirochaeta icterohaemorrhagiae* in this disease is discussed at some length, and the proof that it is the causal agent is established in a later part of this paper. We may anticipate by here stating (1) that the spirochaete may be found in the human peripheral blood stream; (2) that injection of infected human blood into the peritoneal cavity of the guinea-pig may produce a characteristic fatal illness in that animal, in whose tissues *post mortem* the spirochaetes are present in large numbers; (3) that after the first fortnight of the disease the spirochaete may be found in the patient's urine.

In the early stages of this disease the most rapid and the most certain criterion in diagnosis lies in the discovery of the spirochaete in the peripheral blood stream. As the incubation period of the disease in the guinea-pig is at least six days, it would require a wait of at least eight days before the development of the disease in the guinea-pig could establish the diagnosis. After the second week of illness the discovery of the spirochaete in the urine is sufficient evidence of the disease. These various criteria presuppose the employment of complete bacteriological equipment in the hands of experienced observers. These are not always at hand, and reliance has to be placed on the correct interpretation of the clinical signs and

symptoms. The sudden onset with headache, generalized pains, and a sense of utter exhaustion, vomiting, conjunctival congestion, herpes labialis, and a temperature of 103° to 104°, with jaundice appearing on the fourth or fifth day, make the diagnosis of spirochaetosis icterohaemorrhagica almost certain.

In France the chief causes of jaundice have been the *Spirochaeta icterohaemorrhagiae*, and members of the enteric group of organisms. Jaundice in typhoid or paratyphoid fever usually appears about the end of the second week. There are cases, however, of paratyphoid fever in which the jaundice appears as early as it does in spirochaetosis icterohaemorrhagica. The difficulty in diagnosis is then considerable. At the end of the first week help can be obtained in differentiating the two diseases by means of the atropine test. This test was introduced in the diagnosis of typhoid fever by Captain H. F. Marris, R.A.M.C. One-thirtieth of a grain of atropine sulphate is administered hypodermically, and the increase of pulse rate is recorded every minute for the following hour. If the rate of the heart only increases by ten beats or less, this is evidence that the patient is suffering from typhoid or paratyphoid fever. It is important to bear in mind that the rate of the heart before the injection must not be above 80 to 85 per minute. If the rate increases from 100 to 110 or 115 after the injection of atropine sulphate it is impossible to be certain whether the escape of 10 to 15 beats indicates a positive or negative result. It is rare that the organism can be isolated from the blood in the prevailing enteric group of diseases. In inoculated patients it is necessary to trace the agglutination curve from three to four readings. This means a delay of at least fourteen days after the first sample of blood has been taken.

Apart from these specific methods of differential diagnosis or the presence of a typical clinical picture there can be mere speculation.

Spirochaetal Infection without Jaundice.

It is almost certain that many cases of "P.U.O." in France have been due to the *Spirochaeta icterohaemorrhagiae*, and in the absence of jaundice the difficulty in diagnosis may be great. It is becoming more generally recognized that this same spirochaete may give rise to a clinical picture in which there is an absence of jaundice. The following case illustrates this point.

Sudden onset with body pains, frontal headache, photophobia, and vomiting. Temperature on the first day 104°, pulse 100, and the patient was very ill. The conjunctivae were injected; herpes labialis was present, the spleen was not palpable; the urine showed on heating a thick cloud of albumin, but no bile. Bilious vomiting was persistent for several days.

By the fourteenth day the patient appeared convalescent, but on the twentieth day there was a return of fever and pains, which lasted for five days. After this recovery was slow, but continuous. Nine weeks after the onset spirochaetes were still present in the urine, though health was nearly re-established. At no time was there jaundice or bile pigment in the urine.

On the third day of illness 2½ c.cm. of the patient's blood were injected into the peritoneal cavity of a guinea-pig, which subsequently developed jaundice, and after death spirochaetes were to be seen in the sections of its liver.

For most of this record we are indebted to Captain H. Carson, R.A.M.C.

Costa and Troisier have shown that in certain cases which present meningeal symptoms the cerebro-spinal fluid produces the characteristic disease in the guinea-pig. It is therefore necessary to bear this fact in mind in the elucidation of any case of fever presenting pronounced meningeal signs and symptoms.

It is unnecessary to pursue the differentiation of this disease with jaundice from the common affections of the biliary system associated with jaundice. Nor is it necessary to mention the various febrile diseases which might be confused with spirochaetosis icterohaemorrhagica before the development of jaundice, or with that type of the infection in which jaundice is altogether absent.

CLINICAL PATHOLOGY.

Apart from the finding of the spirochaete in the blood stream and the injection of infected blood into the guinea-pig, which are discussed below, examination of the

peripheral blood reveals the following departures from the normal state. In all severe cases there is a slight anaemia, the average red cell count being 4 to $4\frac{1}{2}$ million per c.mm., and the haemoglobin percentage is reduced to 80 to 90 per cent. Some cases become very anaemic, and in one case the red cells numbered 2½ million per c.mm. There is invariably a leucocytosis, amounting in some cases to 25,000 per c.mm. Differential counts show a relative increase of the polymorphonuclear leucocytes to 75 to 80 per cent.

The fragility of the red cells has been frequently tested and is found to be either normal or slightly diminished. No abnormal red cells have ever been detected. It is certain, therefore, that the jaundice is not of haemolytic origin.

As there was evidence that the jaundice was due to some obstruction in the biliary passages, and as the *post-mortem* examination on two cases suggested an inflammation of the duodenum, attempts were made on many occasions to siphon off the duodenal contents by means of an Einhorn tube. Though no spirochaete was ever detected in the fluid so obtained, the finding of catarrhal cells in large numbers suggested the presence of a duodenitis in some cases.

Many of our cases in whom the spirochaete was discovered were investigated thoroughly from the point of view of the enteric group. The examinations were always negative, both from blood culture and from a study of the agglutination curve.

MORBID ANATOMY.

The opportunities of *post-mortem* examination have been few, and the following account is based on four cases in our own series and the accounts of four *post-mortem* examinations described by Captain Stokes and others. Six patients died on the ninth, twelfth, thirteenth, fourteenth, seventeenth, and twenty-eighth days respectively, and one patient, in whom the date of onset was doubtful, died on the fourth day after admission to a casualty clearing station.

All the bodies were deeply jaundiced with the exception of the case who had died on the twenty-eighth day.

The Stomach and Intestines.—As the jaundice in these cases appeared to be of the obstructive type, special attention was given to the condition of the duodenum, and in three of our cases the appearances pointed to a duodenitis. The mucous membrane was of a bluish-red colour, and the Brunner's glands appeared through the mucous membrane as small yellow, opaque areas, from the size of a pinhead to that of a split pea. The whole of the mucous membrane had a swollen, watery appearance. In these cases the area round the ampulla of Vater seemed to be particularly affected. Other cases did not show this same duodenal condition, and microscopic examination did not give any evidence of recent or old inflammation.

In one case there was a considerable submucous haemorrhage in the stomach, and in another a polypoid condition of the mucous membrane at the pyloric end. Scattered subperitoneal haemorrhages were commonly found over the small intestine. No noteworthy lesions were discovered in the mucous membrane of the small or large intestine in any other case. The omental glands were usually enlarged.

The Liver and Bile Passages.—Particular attention has been given to the naked eye and microscopic appearances of the larger bile passages. These were normal in appearance and showed no evidence of inflammation except in the last half-inch of the common duct lying within the duodenal wall. This was swollen and of bluish colour in resemblance to the duodenal mucous membrane. In one instance a probe passed along the common duct into the duodenum dislodged a formed plug which was impacted in the ampulla. A film made from this plug showed numerous epithelial cell nuclei embedded in a matrix of mucin.

In all cases the liver to the naked eye was normal in pattern and texture, though sometimes altered in colour, due to bile stasis. Microscopically its appearances varied. In one group the cells of the lobules were natural in arrangement and appearance, and, apart from evidence of biliary stasis, the only abnormal feature was the presence of collections of cells in the portal areas, such as occur in other diseases. (Figs. 1 and 2.) In another

group the liver cells were dissociated (Fig. 4), and many were markedly enlarged and contained well-stained nuclei. Collections of such hypertrophied cells, with clear pale protoplasm, appeared, especially just beneath the capsule. Many liver cells contained two nuclei, and mitoses were numerous. Staining with Sudan III showed a very little fat, in the form of fine droplets, which were partly within the endothelium (Kupffer's cells).

The sum of these changes suggests the effect of damage which has been insufficient to cause extensive necrosis, but has acted as a stimulant to cell growth. In addition, the portal areas show collections of small mononuclear cells and polymorphs, and towards the centres of the lobules both intracellular and extracellular granules and masses of pigment were found. These microscopic changes resemble those described by Beitzke and Herxheimer.

In one case there were only slight changes—namely, variations in the sizes of the nuclei, a few mitoses, vacuolation of the central cells of the lobules, and in one place a hepatic venule was filled with a mass of dissociated liver cells mingled with red blood corpuscles. A film made from a scraping of this liver showed one characteristic spirochaete. Stokes in two cases describes an exudation of cells into the interstitial tissue surrounding the smaller bile ducts. He detected leucocytes lying "between the liver columns, and usually between the vessels."

The Kidneys.—Stokes described the lesions in the kidneys under three headings: (1) Swelling and granular degeneration of the tubular epithelium, particularly of the proximal convoluted tubules and the ascending loops of Henle; (2) an exudation of polymorphonuclear leucocytes between the tubules and, more rarely, within them; (3) haemorrhages into the lumen of the tubules in poorly defined patches.

The glomeruli showed no changes in particular.

The Spleen.—In no case was there any enlargement or any sign of involvement of this organ. This harmonizes with the clinical observation that the spleen is not usually enlarged in this disease.

The pancreas was firm and to naked eye and microscopic examination was perfectly normal.

The Lungs.—In all our cases there were haemorrhages in the lungs, in two cases reaching the size and consistence which is met with in cases of mitral stenosis. There was nothing noteworthy in any of the other organs of the body. Stokes showed the presence of the spirochaete in the kidney in one of his cases. In no other morbid human tissue has he or have we been able to detect it.

EXPERIMENTAL PATHOLOGY.

I. HISTORICAL.

It is to the Japanese workers Inada and Ido that we owe the discovery of the *Spirochaeta icterohaemorrhagiae*. In November, 1914, they announced the discovery of a spirochaete in the liver of a guinea-pig which had developed jaundice and died as the result of the inoculation of blood from a case of jaundice, epidemics of which they were investigating in conjunction with Hoki, Kaneko, Ito, and Matsuzaki. This finding they were able to repeat, the spirochaete being found in the liver and blood of the infected animals in large numbers. The infection was shown to be transmissible from animal to animal. Later these Japanese workers were able to demonstrate the specificity of this spirochaete, the finding of it in the patient's blood in six cases, in the tissues in two fatal cases, and the discovery of protective substances against it in the serum of patients recovering from the disease putting this question beyond doubt. Similar findings were announced by the German workers Hübener and Reiter, Uhlenbuth and Fromme, and Beitzke, obtained by them during investigations of the jaundice epidemic amongst their troops. No mention, however, is made by them of the Japanese work. The researches of Stokes, Ryle and Tytler, Dawson and Hume, on the British front, and later those of Martin and Pettit, Garnier and Reilly, Costa and Troisier in the French army, have shown that a similar type of jaundice is epidemic on the Western front, findings corresponding with those of the Japanese having been obtained.

II. EXPERIMENTAL INOCULATION.

Attempts to reproduce this condition in animals have shown that the guinea-pig is the animal of choice, the monkey and rabbit being more or less immune, whilst the

mouse and white rat occupy an intermediate position. The guinea pig can be infected by the intraperitoneal injection of the patient's blood or urine. In the case of blood, success can only be looked for with any degree of certainty if it is taken early in the disease—fourth or fifth day—and though the blood may still be infective as late as the seventh, eighth, or ninth day, later than that period the results are almost always negative. The intraperitoneal injection of 3 to 5 c.cm. of blood gives the most satisfactory results. As regards the infectivity of the urine for the guinea-pig, some difference of opinion seems to exist. The Japanese authors claim that the patient's urine is infectious for the animal early in the disease, and as in the case of the blood, this diminishes as the disease progresses. They have, however, had positive results as late as the twenty-first day. On the other hand, Garnier and Reilly claim that it is only from the tenth to eleventh day onwards that the urine is capable of infecting the guinea-pig, that is to say, from the time the spirochaete can first be demonstrated in the urine microscopically, and that earlier in the disease the results of their experiments have been consistently negative. Stokes's attempts in this direction were on no single occasion attended with success, despite the fact that the centrifugized deposit from large quantities of urine was employed and the attempts were made at various periods of the disease. Our experiments, though few in number, were negative.

The Disease in the Guinea-pig.

The disease in the guinea-pig is characterized by jaundice, haemorrhages, conjunctival congestion, albuminuria, and pyrexia. It is nearly always fatal. The incubation period in the animals injected with the patient's blood is somewhat variable—from six to thirteen days. Stokes quotes a case in which it would appear to have been as long as eighty-six days. After several passages of a strain the incubation period is gradually reduced until it reaches a point where it remains more or less constant, between four and five days. The mode of inoculation naturally affects the incubation period, it being longer when the infectious material is injected subcutaneously. The disease is ushered in by a sharp rise in temperature, the animal is quiet and refuses to eat. A temperature of 103° F. is the rule, though it may rise to as much as 106° F. Jaundice appears when the temperature has reached its maximum, the animal becomes more acutely ill, and usually twenty-four hours after its appearance we have a fall of temperature to subnormal, collapse, and death. Spirochaetes appear in the blood with the onset of pyrexia (Fig. 3), and can be demonstrated in the urine *ante mortem*. Conjunctival congestion is usually present, skin haemorrhages and haematuria are not infrequent.

Blood Changes in the Guinea-pig.

Anaemia towards the end of the disease in the animal, according to Stokes, is marked and accompanied by a fall in the leucocyte count. Our observations, though few in number, do not bear out this statement, a moderate degree of anaemia only, and a polymorphonuclear leucocytosis with a total white count of from 18,000 to 25,000 being noticed. These findings bear out those of Dawson and Hume in this disease in man, a moderate polymorphonuclear leucocytosis being a constant feature. Apart from a certain degree of polychromasia, we have not found any changes on the part of the red cells.

Pathological Changes in the Guinea-pig.

The findings in guinea-pigs which have died of the disease, or which have been killed after the appearance of the jaundice, are characteristic. We have jaundice of varying intensity of the skin and all internal surfaces. As a rule the jaundice is marked, but occasionally, as in man, one meets with cases which show little or none. This is, however, a rare occurrence. Fine petechial haemorrhages are seen in the skin, subperitoneally and in the muscles, particularly those of the thighs and abdominal walls. The loose areolar tissue of the groins, axillae, and cervical regions shows haemorrhages of varying size, and the lymph glands in these regions are enlarged and frequently haemorrhagic. The post-peritoneal tissue also shows numerous haemorrhages, particularly in the region of the kidney, that organ being frequently surrounded by a layer

of free blood. The small bowel is usually congested, and in the larger percentage of cases shows numerous subserous haemorrhages usually elliptical in shape. On opening the gut it is occasionally noticed that the duodenum, particularly in its upper portions, is more congested and the mucosa more swollen than the rest of the small intestine. This same fact was drawn attention to by Dawson and Hume. The large bowel may show little or nothing, or it may be the site of areas of haemorrhage, which vary from clusters of pin-point haemorrhages to areas 0.5 to 1 cm. in diameter, which suggest the commencement of ulcer formation.

The kidneys are acutely congested and show minute haemorrhages, subcapsular and throughout the cortex. The suprarenals are usually the site of large haemorrhages, as is the case in any acute toxæmia in the guinea-pig. The liver, as a rule, shows no macroscopic changes. The spleen is congested, friable, and in the majority of our cases showed distinct enlargement, though Stokes describes it as "not obviously enlarged." The epididymis and testicle may also show haemorrhages. The lungs show the most characteristic changes in the shape of multiple clear-cut haemorrhages, varying in size from that of a pinhead to a threepenny-piece, and giving rise to that appearance which the Japanese authors very happily describe as being like "the wings of a mottled butterfly." As pointed out by Stokes, the larger haemorrhages are usually confined to the lower lobes and may be arranged symmetrically along the lateral margins of them. He also draws attention to the fact that these haemorrhages in the lungs and intestine are of early appearance, having been noticed by him in animals killed twenty-four hours after injection. The heart, as a rule, shows nothing, but, as in the case of other viscera, it is sometimes the site of small haemorrhages.

Pathological Histology.

Liver.—The changes seen in the liver may vary from cloudy swelling to acute parenchymatous degeneration, small prescribed areas of cell necrosis sometimes being found on section. According to the Japanese, the biliary ducts show no congestion, but Stokes describes an inflammatory process about the smaller bile ducts with a leucocytic infiltration of the affected areas—a pericholangitis—and to this he is inclined to attribute the jaundice.

Kidney.—This organ shows those changes characteristic of an acute parenchymatous nephritis. The tubular epithelium shows degenerative changes, in many cases both marked and extensive. There is a leucocytic infiltration of varying degree around the affected tubules, and not infrequently the affected tubules in places are packed with leucocytes. Haemorrhages occur throughout the cortex and many tubules are seen to be filled with red cells. These degenerative processes fall chiefly on the proximal convoluted tubules and the thicker portion of the loop of Henle, the glomeruli as a rule not being markedly affected.

Suprarenals.—Almost invariably these organs are haemorrhagic, and in acute cases they show haemorrhages involving practically the whole of their structure. The haemorrhages apparently originate in the medulla.

Lymphoid Tissue.—The spleen, lymph nodes, and Peyer's patches all show congestion and some endothelial proliferation. The spleen shows evidence of increased blood destruction, the sinuses being packed with macrophages containing red cells; free pigment and leucocytes are also present. The lymph glands occasionally show haemorrhage, and the Peyer's patches are usually surrounded by haemorrhage in the form of a thin layer of free blood, and also show extravasated blood throughout the lymphoid tissue.

Lungs.—The haemorrhages in the lungs are seen to be pyramidal in shape, with their base lying against the pleura. They are frequently limited by the boundaries of the lobule. The vessels leading to these areas of haemorrhage are frequently seen to be packed with leucocytes, and Stokes describes cases in which thrombi have been noticed in these vessels, though he does not consider the evidence sufficient to attribute the haemorrhages to these thrombi.

Distribution of the Spirochaete in the Guinea-pig.—The spirochaete lives and multiplies in the blood stream and in various organs. It is usually extracellular, and when

present in the tissues it is found in the interstitial tissue, or more rarely in the endothelium or in the phagocytic cells. In the guinea-pig, unlike the case in man, it is found with ease in the blood of the jaundiced animal, especially in the case of a strain which has gone through several animal passages and kills the animal rapidly. The liver contains the spirochaete in great numbers, and it is sufficient to make a smear from a portion of this organ to have a preparation showing a dozen or more spirochaetes per oil-immersion field. In stained sections the spirochaetes are seen to be numerous and extracellular for the most part, forming when very numerous a sort of garland round the individual cells. After the liver, the kidneys and suprarenals contain the largest number of spirochaetes. In the kidney they occur in the interstitial tissue between the tubules and also in the walls and lumen of the tubules themselves. Unlike the case in the liver, their distribution in the kidney is by no means general but is limited to areas, where, however, they are numerous. Although comparatively numerous in the blood stream, the spleen and bone marrow contain few. The lymphoid tissue (splenic follicles and lymph glands) also shows but few spirochaetes, and in the lungs, heart muscle, striated muscle and arterial walls they are rare. They are numerous in the urine from the commencement of the jaundice. Though the foregoing description of the distribution of the spirochaete in the diseased guinea-pig is true for the majority of cases, one occasionally meets with animals in which the spirochaete is only found with difficulty. It may be stated as a general rule, however, that those animals showing the most marked lesions contain the most spirochaetes.

Mode of Excretion.—In the guinea-pig the spirochaete is excreted in the bile, faeces, and urine, though it is only in the latter that it is with any ease demonstrated microscopically. The Japanese workers have shown, however, that all three are infective for the guinea-pig, their experiments with the bile of infected animals giving a greater percentage of successful results than those with the faeces and urine, despite the fact that on no single occasion were they able to demonstrate the spirochaete microscopically in it.

Technique of Transfer.—The disease can be transmitted from animal to animal most surely by employing the heart blood or the emulsion of liver of a diseased animal. Inada states that he found the former, injected in quantities of 2 c.cm., the most satisfactory, but our findings and those of Stokes would point to the emulsion of liver being the more certain of the two. In the case of the heart blood all that is necessary is to collect the blood with the usual precautions as regards sterility and to inject it intraperitoneally into the fresh guinea-pig. If the liver emulsion is to be employed, the liver is removed as rapidly as possible after opening the animal, using the greatest possible care to avoid contamination, and is placed in a sterile vessel, where it is roughly ground up with a small quantity of normal saline. The resulting emulsion is then rapidly centrifuged to throw down the lumps of liver tissue, which would block the needle, and the fluid so obtained injected intraperitoneally or subcutaneously. The employment of a large-bored needle will be found advisable, and in all cases where a possible contamination is suspected, such as invasion of the liver tissue by bacteria *post mortem* should the animal have been dead some little time, the subcutaneous route for inoculation is the one of choice. In a like manner an emulsion of any other organ containing the spirochaete, such as the kidney or suprarenal, could be employed. Besides the subcutaneous and intraperitoneal methods of inoculation which are employed as a rule owing to their simplicity, the guinea-pig can be infected by way of the mouth, feeding the animal on food soaked in liver emulsion, by applying the virus to one of the available mucous surfaces, and by smearing it on to the shaved skin.

III. MORPHOLOGY.

Microscopical Appearance.

This organism is fairly pleomorphic, and varies in length from 4μ to 25μ , with an average length of 8 to 9μ . Its thickness varies with the staining method employed, but the Japanese workers are of the opinion that it is probably about 0.25μ . The ends are sharp and pointed, and are in most cases hooked, not uncommonly both ends being bent to the same side in the form of a letter C, or one end is

bent in an opposite direction to the other, giving the parasite an S-shaped form. The spirochaete, unlike *Treponema pallidum*, shows irregular undulations usually composed of 2 to 3 large or 4 to 5 smaller waves. This is not always the case, Martin and Pettit pointing out that occasionally one comes across forms in which the waves are more numerous and more regular, the parasite approaching more the form of *T. pallidum*. In the blood the spirochaete conforms to the typical form, except in those severe infections where it is very numerous, and then one meets with parasites bent in the form of a ring or twined one about another. On the other hand, the forms met with in the liver vary much in shape and length. One sees straight forms, others bent at one end only, giving the parasite the appearance of a note of interrogation, and again others showing round or oblong granules, 3 to 4 in number, staining a deep purple with Giemsa. Still larger granules may sometimes be observed projecting from the body of the spirochaete—the so-called “lateral bud” of the spirochaete already described in the case of other varieties—the significance of which is not apparent. Degenerative forms are also met with which are thick, devoid of waves, and blunt at the ends. Flagella were not described by the Japanese, but Martin and Pettit and Vaudremer in a recent publication describe flagella, which they have been able to demonstrate by Löffler's and Van Ermengem's staining methods. These are terminally placed, and vary in number and length. Further, they have been able to show that the flagellum ends in a small circular knob, the significance of which has yet to be elucidated.

Staining Methods.—Unstained in a hanging drop preparation, the spirochaete is invisible with the ordinary microscope except when very numerous, and even then its presence is detected only with the greatest difficulty.

Dark-ground Illumination.—By this means the spirochaete can be readily studied. It is not nearly so refractile as *T. pallidum*, and its movements are much more sluggish. As a rule it remains motionless, or is simply carried across the field by the currents set up between the slide and cover-slip. It is, however, capable of lashing movements of the extremities, the centre portion of the parasite remaining rigid, or it may show twisting worm-like movements.

Dried Smears.—Smears of blood, tissues, or urine sediment can be readily stained by Giemsa, Leishman, Tribondeau, or a rapid silver impregnation method such as Fontana. With Giemsa, after a preliminary fixation with methyl alcohol, absolute alcohol, or osmic acid, the preparation is stained for two hours with a mixture of 20 drops of stain in 10 c.cm. of water. Generally speaking, when the leucocytic granules are deeply stained, the spirochaete will be found to be stained. With Leishman, after the preliminary fixation for one minute with undiluted stain, the diluted stain is allowed to act for thirty minutes. This gives quite satisfactory results, and though not deeply stained the spirochaete is readily visible. Coloured by these methods, the spirochaete has a pinkish-purple tint. Burri's Indian ink method and similar processes give us a rapid and satisfactory means of demonstrating the spirochaete in smear preparations, but perhaps the most satisfactory of all is that of Fontana, which consists of staining the preparation with an ammoniated silver nitrate solution after a preliminary mordancing with 5 per cent. aqueous solution of tannic acid.

Staining of Sections.—The most satisfactory staining process for sections will be found to be the older Levaditi method.

Staining of Flagella.—For this purpose the methods of Löffler and Van Ermengem both give satisfactory results. The following are the directions given by Martin, Pettit, and Vaudremer:

(a) **Löffler.** Fix in ether-alcohol. Cover the preparation with Löffler's fuchsin ink and heat gently, stopping the heating as soon as the preparation commences to steam. Wash in distilled water, and then three times with absolute alcohol. Stain with alkaline aniline gentian violet, warming gently. Wash in distilled water and dry.

(b) **Van Ermengem.** Follow the classical technique, but in place of Ziehl's carbol fuchsin stain the preparation with alkaline aniline gentian violet, diluted so as to obtain a background not too deeply stained.

IV. CULTIVATION EXPERIMENTS.

The first successful attempts to cultivate the spirochaete were those of the Japanese Ito and Matsuzaki,

Starting from the infected guinea-pig, the spirochaete was obtained in pure culture by the method of Noguchi, guinea-pig kidney replacing that of the rabbit usually employed. The cultures were covered by a layer of liquid paraffin. The best results were obtained at a temperature of 22° to 25° C. They noticed that growth commenced in from three to seven days, or rarely after a delay of as much as two weeks, that the first generation lived for three to six weeks, and that the lives of the succeeding generations were rather shorter. Since then they have succeeded in growing the organism on various different media, solid and liquid—blood agar and gelatin, human serum, diluted ox serum and ascitic fluid. Martin and Pettit in repeating this work have been unable to obtain cultures on solid media, but, however, have been successful with various liquid media. The most satisfactory they found to be diluted rabbit serum (1 in 5 of normal saline), and diluted ox serum (1 in 9 of normal saline), without the addition of pieces of tissue, but merely covered with a layer of liquid paraffin. The organism grows well at a temperature of between 25° and 32° C., refusing to grow at 37° C. or only after acclimatization. The cultures are inoculated with the heart blood or emulsion of liver of a jaundiced guinea-pig which has been preferably killed and not allowed to die of the disease. The cultures remain clear, any cloudiness or turbidity being an indication of contamination and of failure because the spirochaete refuses to grow, or only shows feeble growth in the presence of other organisms. The cultures are without odour and ascitic fluid remains uncoagulated. In culture the spirochaete is evenly distributed throughout the media, and is shorter and more active than when seen in the tissues. Occasionally one sees several spirochaetes intertwined together in the form of a rosette, and here and there individuals of exceptional length. As the culture becomes older the organism becomes less active, and degeneration forms make their appearance. Subcultivation should be practised when growth is at its height, that is, when spirochaetes are numerous and active. The cultures are capable of reproducing the disease in the guinea-pig, and their virulence is maintained up to the twenty-second day.

V. MODE OF SPREAD OF THE DISEASE.

In their first communication the Japanese authors expressed the opinion that infection occurred through the skin or by the mouth. As was shown by them, the spirochaete is excreted chiefly by way of the urine, which provides a ready means for the dissemination of the virus. They had noticed, also, that epidemics of jaundice occurring in mines were confined to "wet" mines, and that if in a mine the cases came from one particular portion, that portion of the mine was invariably a flooded one. The animal experiments performed by them showed that the guinea-pig could be readily infected by way of the mouth, or by simply applying the infectious material to the shaved skin, abraded or intact—five minutes' contact being sufficient for infection to have taken place. Knowing these facts it seemed probable that in these epidemics, in the mines at any rate, the water having been contaminated by urine the spirochaete gained entrance to its new host via the skin or by the mouth. This was further borne out by the fact that when the flooded portions of the mine were pumped dry the incidence greatly decreased. In the communication of Stokes, Ryle and Tytler attention is drawn to the fact that the cases of jaundice occurring in this sector of the line came almost exclusively from one or two portions of the front line trench, and that as soon as the units were moved out of these particular trenches they ceased to have cases of jaundice, and in a similar manner fresh units moving into them, who had had no cases up to that time, almost immediately commenced to develop them. These portions of trench when compared with the rest of the line were distinguished from the remainder by always being in a very wet condition, it being impossible to drain them properly. In their first paper the Japanese discussed the possibility of biting insects, such as the flea or mosquito, playing a part in the spread of the disease from man to man, but concluded that the smallness of the numbers of the spirochaetes in the peripheral circulation made it very doubtful. Stokes also undertook experiments with a view to finding out if the body louse, so common amongst the troops, could be incriminated. When one considers, however, how general

the distribution of the louse is, and how localized the areas from which cases of jaundice come, this does not seem probable. His experiments proved negative. In a recent communication the Japanese state that they have been able to show the presence of the spirochaete in 38 per cent. of the field rats coming from areas in which jaundice was epidemic, and they suggest that the infection may be conveyed by the rats' urine directly or indirectly. Stokes has been able to confirm this finding, six out of fifteen rats caught in these areas in which jaundice was endemic having been shown to contain the spirochaete in the kidney capable of producing the disease in the guinea-pig. It would appear, therefore, that the rat acts as a reservoir for the infective agent, spreading the disease by means of its urine directly or indirectly, and that infection is further spread by the patient's urine and faeces.

VI. IMMUNITY.

The Japanese in their first paper pointed out that the blood of convalescent patients contained protective substances capable of neutralizing the virus *in vitro*, and of protecting the guinea-pig against infection. This substance is first demonstrable in the blood serum after the tenth day of illness, but, as a rule, is not found before the fifteenth to the twentieth day. This immune substance persists in the blood for a long time, the Japanese authors quoting two cases in which it was detected at the end of five and a half years. It is specific, and is not present in the serum of healthy persons, nor in the serum from cases of jaundice of other origin.

The immune substances can be demonstrated by the reaction of Pfeiffer, the results of the experiment being confirmed by the subsequent condition of the guinea-pigs, the control animal developing jaundice and dying, while the other which received the virus and the patient's serum remains unaffected. They also showed that this substance was endowed with curative properties, the diseased guinea-pig being cured by an injection of the patient's serum if it was administered before the onset of jaundice. These facts have been confirmed by the French and by Stokes, the latter having shown that even after the appearance of jaundice the guinea pig can be cured, provided the serum is injected before the collapsed stage is reached. In view of these facts, the Japanese have prepared an antiserum by immunizing a horse, and report encouraging results from the employment of this serum therapeutically. The French also are preparing an antiserum, but so far have published no results of its application in the disease.

Attempts have also been made to demonstrate immune bodies in the patient's serum by means of the reaction of the fixation of complement. As antigen an emulsion of liver rich in spirochaetes was employed. Stokes reports negative results with this reaction, and, while Martin and Pettit state that it was positive in the five cases in which it was tried by them, they at the same time admit that a strongly syphilitic serum gave a positive result also.

The serum of the patient, according to Garnier and Reilly, does not agglutinate the spirochaetes, whereas the Pasteur Institute serum agglutinates them readily, the spirochaetes losing their mobility and running together into clumps.

VII. BACTERIOLOGICAL DIAGNOSIS.

Direct Examination of the Blood.

Owing to the shortness of the period during which the organism is to be found in the circulation and the smallness of its numbers when present therein, the direct examination of blood smears for the spirochaete is of little value as a practical method of diagnosis. However, in the early stages of disease (up to the seventh day) it is sometimes possible to demonstrate the spirochaete in this manner, and, seeing that it requires little time or trouble, it is worthy of trial. The blood may be examined by means of the ultra-microscope; blood smears may be stained by Giemsa, Leishman, and Fontana, or preparations made with Burri's Indian ink method.

Animal Inoculation.

The reproduction of the disease in the guinea-pig by the injection of the patient's blood or urine is undoubtedly the most satisfactory and convincing diagnostic test we at present possess, but unfortunately, owing to the fact that it is only in the early stages of the disease that the blood

is infective and that the infectivity of the urine is a very variable quantity, this method of diagnosis as a practical measure has its limitations. In the early days of the disease, up to the seventh or even ninth day, one, or preferably two, guinea-pigs should be inoculated intraperitoneally with 3 to 5 c.cm. of the patient's blood. Injection of larger quantities of blood is of itself sufficient frequently to kill the guinea-pig. In a positive case, after an incubation period of from six to twelve days, the animal develops the disease and dies, showing the characteristic changes already described. Similarly, in the early days of the disease the injection of the urine into the guinea-pig should be done, and even after the blood has ceased to be infective and the case is well advanced, it is perhaps worthy of trial, because, as shown by Garnier and Reilly, positive results may be obtained as late as the twenty-eighth day. These workers inject the centrifugalized deposit from 40 to 60 c.cm. (occasionally as much as 150 to 250 c.cm.) of recently passed urine, suspended in 5 c.cm. normal saline. Naturally all precautions as regards sterility must be observed in the collection and centrifugalization of the urine.

Examination of the Urine for *Spirochaetes*.

As pointed out by the Japanese, the spirochaete is eliminated chiefly by way of the kidney, and from the ninth day onwards can be demonstrated microscopically in the urine. At first it appears in the urine in small numbers only, the number gradually increasing to a maximum reached about the thirteenth to fifteenth day of disease, to diminish again and finally disappear from the urine about the fifth or beginning of the sixth week of illness. Should, therefore, a case of jaundice present itself too late in the disease to make the injection of the guinea-pig with the blood of no use, and should the injection of a guinea-pig with the urine have proved negative, the demonstration of the spirochaete in the urine gives us valuable information as to the cause of the jaundice. The procedure is simple and is as follows: The urine is collected in a sterile vessel and 50 c.cm. or so centrifuged. The deposit so obtained is washed with distilled sterile water and recentrifuged and smears made with the final deposit. Preparations can be made by the Indian ink method, Harrison's collargol method, or with a 2 per cent. aqueous solution of Congo red, treating the smear so obtained with 1 per cent. HCl in alcohol, as recommended by Benians. These methods have the advantages of rapidity and simplicity, but in our opinion the best is the staining of dried smears by the method of Fontana. Should, therefore, the urine of a case of jaundice, examined in this manner towards the end of the second or beginning of the third week, show the presence of numerous spirochaetes having the morphological characters of the *Spirochaeta icterohaemorrhagiae* already described, and should the case have been proved negative for the enteric group by blood culture, examination of stools and urine for bacilli or by agglutination, there is little doubt that the case in question is one of spirochaetosis. It must be borne in mind, however, that it is not sufficient to examine the urine on one occasion only, but several examinations at intervals of two to three days may be necessary before the spirochaete is found. Even then, as pointed out by Stokes, we may fail to find the spirochaete because it is to be expected that in mild cases the numbers excreted will be small, and the period during which they are to be found in the urine transient. It cannot be claimed, however, that this method of diagnosis has the same value as the production of jaundice in the guinea-pig as there are certain obvious sources of error. These are the limitation of the microscope when used alone to determine the species of micro-organism with which one is dealing and the presence of other bodies in the preparation resembling spirochaetes liable to mislead an inexperienced observer. The latter error should not be made by a skilled worker, and though the examination by us of control urines from cases of scarlet fever, measles, lobar pneumonia, typhoid and paratyphoid fever have occasionally revealed the presence of spirochaetes, this has been of rare occurrence, and in no case did these spirochaetes or spirilla bear any morphological resemblance to the *Spirochaeta icterohaemorrhagiae*. We have, therefore, concluded that in a case of jaundice the clinical symptoms of which point to spirochaetosis, which has been proved negative to the enteric

group, and in the urine of which spirochaetes with the morphology of *Spirochaeta icterohaemorrhagiae* have been found, one is in possession of a chain of evidence warranting the diagnosis of spirochaetal jaundice.

Immunity Reactions.

1. *Reaction of Neutralization*.—This reaction, already referred to under the heading of immunity, can be made use of in diagnosis. It suffices to mix a toxic dose of virus (liver emulsion) with 1 to 2 c.cm. of the serum from the case in question and to inject it into a guinea-pig intraperitoneally. The control animal receives the virus alone. If the case is one of spirochaetosis, the guinea-pig remains unaffected, the control animal dying with the characteristic *post-mortem* changes; on the other hand, if the case were not one of spirochaetosis, both animals would develop jaundice.

2. *Fixation of Complement*.—It would not appear that, in our present state of knowledge, this reaction would be of much service in diagnosis. Martin and Pettit report positive results, however, in the five cases in which it was tried by them, but the value of these results was somewhat detracted from by the fact that a strongly syphilitic serum gave a positive result as well with their antigen.

CONCLUSION.

It would seem to be proved that there is in the armies in France a type of infective jaundice which is the same in clinical and pathological features as that described by the Japanese workers, and that this disease is caused by the *Spirochaeta icterohaemorrhagiae*. And there is also undoubted proof that this same spirochaete may cause a similar train of symptoms without the appearance of jaundice.

A complete bibliography is appended, and to the authors of the various publications we acknowledge our debt.

A Clinical Lecture

ON

SOME NOSE AND THROAT DISEASES
OF CHILDHOOD.DELIVERED IN THE ROYAL HOSPITAL FOR SICK CHILDREN,
EDINBURGH.

By DOUGLAS GUTHRIE, M.D., F.R.C.S. EDIN.,

INTERIM SURGEON TO THE EAR AND THROAT DEPARTMENT, ROYAL
HOSPITAL FOR SICK CHILDREN, EDINBURGH.*Adenoids and Enlarged Tonsils.*

LIGHTNING diagnosis is seldom a satisfactory proceeding, but here is a patient whom one is tempted to label at once without further examination. Look at the little girl and note her open mouth, her projecting upper lip, her narrow pinched nostrils and her vacant look. There you have an excellent illustration of the so-called adenoid facies.

The facial expressions of disease were carefully studied by the physicians of last century, but, like the "temperaments," they nowadays receive scant attention. Facial appearances are still worth studying, especially in children, but I would warn you that the adenoid facies is not invariably diagnostic of adenoids. A few weeks ago a boy of 7 was sent to the department to have adenoids removed. Although he had the adenoid facies, I found neither adenoids nor enlarged tonsils. He had, however, a crumpled and deflected nasal septum, obstructing both nostrils, the legacy of a previous injury. Some of you may have seen in Dundas Ward the expressionless child with open mouth and protruding tongue. That child originally came to the throat department. She has no adenoids, but is an example of the Mongol type of idiot. On the other hand, very many children suffering from adenoids show not the least trace of their complaint on their faces.

A certain amount of adenoid tissue is present in the nasopharynx of every child, and between the ages of 2 and 10 it is very liable to hypertrophy. Over 90 per cent. of the children brought to the ear and throat department here are sufferers from adenoids, and the frequency of adenoids among children of school age has been estimated by various authorities at 30 to 40 per cent. The symptoms are very varied. The mother tells you that the child cannot breathe properly, that he snores at night, that his speech is "thick" and muffled, that he continually suffers from colds, that he complains of earache, or that he is backward at school. Epistaxis is also a common symptom.

Many of those children also suffer from enlarged tonsils. If you find the tonsils enlarged there is no need to put your finger into the nasopharynx. Adenoids are certainly present in such a case. You may, however, have large adenoids with tonsils of normal size.

A flow of white gummy mucus from behind the soft palate is often a sign of adenoids, and if you are fortunate you may catch a glimpse of the growths in a post-nasal mirror. By attention to those points one may avoid the disagreeable procedure of palpating the nasopharynx, for which no child will ever forgive its doctor.

On the subject of enlarged tonsils little need be said, but it may be well to remind you of their remote effects. In every child suffering from enlarged tonsils the tonsillar gland is palpable behind the angle of the jaw. This is a significant fact, and the important point to remember is that the tonsils and associated adenoids should be removed before the tubercle bacillus gains admission to the gland through the diseased tonsil. Never forget, therefore, to attend to the tonsils in all cases of enlarged cervical glands.

There is another common disease of childhood which should always lead one to examine the tonsils and that is rheumatism. Some time ago I removed the tonsils of a small boy who was having repeated attacks of "growing pains." One tonsil contained a small abscess the size of a pea. There have been no further attacks of pain since the operation, and I could multiply instances of this nature.

How, then, is the operation to be performed? I beg of you to study the method carefully, for one so often sees cases in which tonsils and adenoids have been incompletely removed. After a thorough operation there is no such thing as recurrence.

Nowadays we prefer to "enucleate" the entire tonsil in its capsule, using a guillotine, of which there are many suitable patterns on the market, and then to clear out the adenoids by means of a curette with a square opening, such as StClair Thomson's. Delstanché's or Gottstein's curettes, which have a triangular opening, are not nearly so effective.

A guillotine which I frequently use when it is important to minimize hæmorrhage is Elphick's hæmostatic guillotine. It is furnished with a crushing blade, which clamps the vessels before the cutting blade is driven home. If complete hæmostasis is desired the clamp may be left on the tonsil stump for several minutes, but, of course, in that case C.E. mixture should be given, as ethyl chloride anaesthesia will not allow sufficient time.

I may summarize as follows the main points in the tonsil and adenoid operation:

Having administered ethyl chloride, introduce the guillotine with its upper surface towards the tonsil, thread it over the tonsil, and dig the point of the instrument well in behind the tonsil, then lever the tonsil forwards so as to produce a swelling on the palate; press upon this swelling with your left thumb, thus forcing the tonsil through the ring of the guillotine. Lastly, drive home the blade and withdraw the guillotine with its lower surface, carrying the tonsil, uppermost.

After removing the tonsils, hook the curette well up behind the palate and shave off the adenoids with a downward sweep.

Foreign Bodies in the Air Passages.

A child was brought here by her mother, who thought she had adenoids. For six months the little girl had been suffering from nasal obstruction and attacks of coughing and sneezing. Observing that the discharge and obstruction were unilateral, I suspected a foreign body, and with some difficulty removed a boot button from the left nostril. Such cases are not uncommon, and the tolerance of the nasal mucosa is rather remarkable. Last year, in France, I removed a fragment of shrapnel from the nasal cavity of a soldier, who had been wounded eighteen months before. It was embedded in the middle turbinal, and the man was unaware of its existence.

When we come to consider the question of foreign bodies in the lower reaches of the respiratory tract—the larynx, trachea, and bronchi—we find that we are dealing with conditions of a much more serious nature.

A great stimulus was given to the study of the subject by the introduction of direct methods of examination. By means of Bruning's and Jackson's tubes we may now inspect the entire tracheo-bronchial tree, and the procedure has been further facilitated by the introduction, by Killian, of suspension-laryngoscopy. The manipulations, however, are difficult, and demand much patience and long practice.

The situations in the air passages in which foreign bodies are most commonly found are the larynx and the right bronchus.

As regards the larynx, it is well to bear in mind that there may be no history of foreign body, but the child may be thought to be suffering from diphtheria or simple laryngitis. This was the case with a boy aged 9, who was admitted to this hospital some months ago. He was kept under observation for a few days, during which time he suffered from dyspnoea, hoarseness, and pain in the larynx. The x-ray photograph showed a distinct shadow in the laryngeal region opposite the fifth cervical vertebra. Direct laryngoscopy was then attempted, and the foreign body, which lay just below the vocal cords, grasped with long forceps; but it was found to be so very firmly impacted that it could only be slightly displaced. Unfortunately, this displacement caused complete obstruction of the airway, and tracheotomy had to be performed. The tracheotomy wound was enlarged and the cricoid cartilage divided, so that the foreign body, which turned out to be a sharp-edged piece of meat bone, could be easily withdrawn. The boy was very ill for several days, but eventually made a good recovery.

When a foreign body passes the larynx it usually lodges in the right bronchus, which, as you may remember, is not only wider than the left bronchus but lies in a more direct line with the trachea.

Bronchoscopy is by no means an easy operation, but if the foreign body be allowed to remain it will almost

certainly set up septic bronchitis and abscess of the lung. Should the direct method be unavailable, tracheotomy had better be performed, as this operation has been proved to have a favourable influence on the mortality rate. Not infrequently the foreign body is coughed out through the tracheotomy wound.

Occasionally children are brought to the hospital who are said to have swallowed some foreign body, usually a coin, and radiography reveals its presence in the oesophagus. There may be no symptoms, as the oesophagus is a very tolerant structure. As a rule, the body is impacted at the entrance to the oesophagus, in the post-cricoid region.

The instrument known as the coin-catcher may be used in removal, or, better still, the more modern and scientific method of oesophagoscopy. It is a much easier proceeding than bronchoscopy.

Laryngeal Diseases in Children.

In conclusion, I wish to direct attention to a few practical points regarding diseases of the larynx in small children. These diseases are difficult to diagnose, and are often a source of much anxiety not only to the parents but to the medical attendant.

The child's larynx is a smaller structure than might be supposed, and its cartilages are very soft. Hence stenosis and suffocation are more liable to occur in children than in adults. Laryngoscopy is more difficult, though in the ordinary routine examination of the throat with a tongue-depressor one often sees the epiglottis in small patients. I have had to allay the fears of more than one anxious mother who thought her child's epiglottis was something pathological. The inferior turbinal bone in the nose is a similar offender, and on three occasions in my experience it has been diagnosed as polypus. Nasal polypus is very rare in childhood.

You may be called out one night to see a child who has suddenly developed a "croupy" cough, accompanied by choking and shortness of breath of a very alarming nature. I need not enlarge on this condition, which is so fully described in textbooks under the various names of "laryngitis stridulosa," "croup," or "spasmodic laryngitis."

The nervous spasm occurring in rickety infants, and known as laryngismus stridulus, is quite a different disorder. The spasm and cyanosis are quite transient, and attacks may come on at any time during the day or night. Treatment should be directed towards the underlying condition.

In both of those diseases remember that adenoids are frequently an important factor in the etiology.

Another laryngeal affection of infancy is congenital laryngeal stridor. It commences at birth or shortly after birth, and consists of a crowing or croaking sound accompanying each respiration. The sound varies in intensity and diminishes during sleep. Thanks to direct laryngoscopy, we now know that the larynx in those cases is backward in its development. The epiglottis is sharply folded upon itself and the arytenoids are closely approximated so that the upper aperture of the larynx is narrowed. No treatment is required, as the condition tends to disappear during the second year of life.

Lastly, I shall merely mention papilloma of the larynx, which must be borne in mind as a possible cause of laryngeal obstruction in children. Its diagnosis is beset with difficulty, tracheotomy is often necessary, and the growths are very liable to recur after removal.

MR. W. B. SMITH, Federal chemist, Kansas, recently reported that court plaster which is being sold throughout the State is full of tetanus bacilli. This report led to the arrest of five Germans. Samples of the plaster are being examined by the United States Department of Justice.

A SOCIETY for American fellowship in French universities has been formed for the purpose of bringing to the notice of American students the extensive facilities offered by French institutions and to induce them to seek there the opportunities for further study which they have hitherto been led to believe were to be found only in Germany. Ten or more graduate fellowships for American students are to be established in French universities to be awarded as the result of competition and to be held for two years. The society has published a book entitled *Science and Learning in France*.

COMBINED VACCINATION WITH MULTIPLE VACCINES (QUADRUPLE, QUINTUPLE, AND SEXTUPLE).

BY

ALDO CASTELLANI, M.D., M.R.C.P.,

LIEUT.-COLONEL ROYAL ITALIAN MEDICAL SERVICE (NAVY),
MEMBER INTERALLIED SANITARY COMMISSION;

AND

FRANK TAYLOR, M.D., M.R.C.P., F.R.C.S., D.P.H.,

LECTURER ON BACTERIOLOGY, UNIVERSITY OF LONDON,
KING'S COLLEGE; PATHOLOGIST, ROYAL WESTMINSTER
OPHTHALMIC HOSPITAL.

THE advantage of using the method of combined vaccinations, introduced by one of us (C.) long ago, is at the present time recognized. The triple vaccine—typhoid + paratyphoid A + paratyphoid B—for instance, prepared and used by one of us since 1905, has recently been adopted in all the allied armies, thanks especially to the work of Dreyer, Walker, Gibson, Bassett-Smith, Cumming and Cummins, Widal, Chantemesse, Vincent, Sergeant, Nègre, Rho, Conte, Porcelli, and others. There are, however, other combined vaccines which will be found useful, and it is on these vaccines—containing, some of them, four, five, and six species of germs—we desire to make some remarks based on a certain amount of experimental work we have carried out.

TETRAVACCINE No. 1 (T.A.B.C.).

Technique of Preparation.—The growth of twenty-four hours typhoid agar cultures is washed off with sterile 0.85 per cent. salt solution to which 0.5 per cent. carbolic acid has been added; the emulsion so obtained is stored at room temperature for twenty-four hours and then standardized.

In some rare cases, when the emulsion is very thick, twenty-four hours may not be sufficient for the small amount of carbolic present to sterilize it completely; the germs, however, will be non-motile, easily counted, and the addition of carbolic salt solution necessary to standardize the vaccine will quickly kill the germs. To standardize the emulsion the bacilli are counted by using a Thoma-Zeiss apparatus, and sufficient carbolic salt solution is added to reduce the number of germs to 2,000 million per cubic centimetre. The standardized emulsion is tested some hours later for sterility. The same procedure is carried out with twenty-four hours old agar cultures of paratyphoid A and paratyphoid B, these two emulsions being standardized to contain 1,000 million organisms per cubic centimetre. The above procedure is also carried out with cholera cultures, the emulsion of which, however, is standardized to contain 8,000 million germs per cubic centimetre. The four standardized emulsions (when found sterile) are mixed together in equal proportions, and the vaccine will therefore contain per cubic centimetre:

Typhoid	500 million
Paratyphoid A	250 "
Paratyphoid B	250 "
Cholera	2,000 "

This mixture, which must be tested for sterility, is the combined vaccine. Of this mixture $\frac{1}{2}$ c.cm. is given under the skin of the arm the first time, and the same, or double the amount, a week later.

Blood Examination of Rabbits Inoculated with Tetravaccine No. 1 (T.A.B.C.).

With the assistance of Mendelson, Porcelli, and others we have carried out experiments on seven rabbits, each of which had received two injections of the tetravaccine, at a week's interval.

The doses given varied between 0.2 c.cm. and 1 c.cm.; the production of agglutinins was investigated in all the seven rabbits, and bacteriolysins in three. The amount of antibodies produced did not seem to be in proportion to the amount of vaccine inoculated; this confirmed the old observation made by one of us, that when immunization is obtained by one injection the production of antibodies is not in proportion to the amount of vaccine injected. Provided a sufficient minimum quantity be given, the same amount of agglutinins, bacteriolysins, etc., will be produced whether one, five, or ten times that minimum dose be given.

The four curves show the agglutinins induced by the injection of tetravaccine in rabbits. They are practically identical with the curves obtained in control rabbits injected with monovaccines.

Agglutination curve for *B. typhosus* in rabbits inoculated twice (at a week's interval) with tetravaccine (T.A.B.C.).

Agglutination curve for *B. paratyphosus* A in rabbits inoculated twice (at a week's interval) with tetravaccine (T.A.B.C.).

Agglutination curve for *B. paratyphosus* B in rabbits inoculated twice (at a week's interval) with tetravaccine (T.A.B.C.).

Agglutination curve for *V. cholerae* in rabbits inoculated twice (at a week's interval) with tetravaccine (T.A.B.C.).

As regards bacteriolysins, in the three rabbits examined they were present for the four species of microbes, and did not seem to be present in smaller amount than in control rabbits inoculated with monovaccines.

Blood Examination of Individuals Inoculated with the Tetravaccine (T.A.B.C.).

The production of agglutinins for typhoid is large, for paratyphoid A and paratyphoid B satisfactory, for

cholera small. The agglutinins present for paratyphoid B are generally in larger amount than for paratyphoid A. The production of agglutinins is not inferior to that found in control individuals inoculated with monovaccines. In fact, not rarely have we noticed that during the first two or three weeks the agglutinins, especially for typhoid and cholera, are in higher amount than in individuals inoculated with monovaccines.

Innocuity of the Tetravaccine (T.A.B.C.).

In Ceylon several thousands of individuals were inoculated in 1913 and 1914, and in Serbia more than 120,000 men were inoculated in 1915 with the tetravaccine by Castellani and Mendelson, Lurie, Mitchell, Slattock, Colonel Randon Head of the French Mission, and others, without any untoward result. It was adopted by the American Red Cross Commission, at the head of which were Drs. R. Strong and T. Jackson. No really serious reaction was ever observed, and the inoculated persons were generally able to attend to their duties in from twenty four to forty-eight hours after injection. The opinion of the medical men in charge of the troops and of the Serbian authorities was very favourable; so much so that the vaccine has recently been adopted officially for the whole of the Serbian army. As regards results, owing to the unfortunate condition of the country elaborate statistics are unobtainable, but the four diseases have been practically absent from the portion of the Serbian army which was inoculated with this vaccine.

TETRAVACCINE No. 2 (T.A.B.M.).

This vaccine consists of an emulsion in carbolyzed saline solution (carbolic acid 0.5 per cent., salt solution 0.85 per cent.) of *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, and *M. melitensis*. In the preparation of the vaccine care should be taken to use a strain of *M. melitensis* rich in antigen, otherwise antibodies for this germ may not develop. The technique is the same as that described in the preparation of the Tetravaccine No. 1 (T.A.B.C.), but agar cultures of *M. melitensis* forty-eight hours old should be used. The technique of preparation is the same as that described above. The growth of the typhoid agar cultures is washed off with 0.85 salt solution containing 0.5 per cent. carbolic acid, is stored at room temperature for eighteen to twenty-four hours, and then standardized in such a way that 1 c.cm. will contain approximately 2,000 million typhoid bacilli. The same technique is used to prepare the paratyphoid A and B vaccines, each of these being standardized to contain 1,000 million. The same technique is used to prepare the Malta fever vaccine, but this vaccine is standardized in such a way as to contain 8,000 million per cubic centimetre.

After standardizing the four different vaccines and testing their sterility they are mixed together in equal parts. The vaccine will contain per cubic centimetre:

Typhoid	500 million
Paratyphoid A	250 "
Paratyphoid B	250 "
Malta fever	2,000 "

Of this vaccine 0.5 c.cm. is injected subcutaneously in the arm, and a week later the same or double the amount is given.

This vaccine has been used in a fairly large number of persons (over 600). The reaction was hardly higher than after the simple typhoid or mixed paratyphoid A and paratyphoid B vaccines. The blood of all inoculated persons examined (24) developed a large amount of agglutinins for typhoid, paratyphoid A and paratyphoid B, and a certain amount for Malta fever, which, however, in several cases, was very small. The amount of agglutinins produced for each germ was apparently not distinctly less than in control individuals inoculated with simple "one disease" vaccines.

PENTAVACCINE No 1 (T.A.B.C.P.).

This combined "five diseases" vaccine consists of a carbolyzed saline emulsion of typhoid, paratyphoid A, and paratyphoid B bacilli, cholera vibrios, and plague bacilli.

Agar cultures twenty-four hours old are used in the case of typhoid, paratyphoid A, paratyphoid B, and cholera; agar cultures three days old are used in the case of plague, as this germ grows slowly. The technique of preparation

is the same as that already described. The vaccine is standardized to contain per cubic centimetre:

<i>B. typhosus</i>	500 million
<i>B. paratyphosus</i> A	250 "
<i>B. paratyphosus</i> B	250 "
<i>V. cholerae</i>	2,000 "
<i>B. pestis</i>	500 "

Half a cubic centimetre is given the first time and double the amount a week later.

Method of Vaccination.

The inoculation is made subcutaneously in the arm in the same manner as when using simple typhoid vaccine. In strong male adults we give 0.5 c.cm. the first time and 1 c.cm. a week later; in adults who do not appear to be very strong and also in women half doses are given with apparently the same satisfactory results. Children between 10 and 16 years of age receive about one-third of the adult dose; children below 10 years of age we have not yet inoculated. The inoculation of the vaccine is followed in a few hours by a local reaction (redness and some infiltration) and general reaction (fever, malaise, rheumatic pains), which generally do not incapacitate for work more than twenty-four to forty-eight hours. The reaction may be said to be, as a rule, much more severe than after the inoculation of simple typhoid, or the mixed typhoid, paratyphoid A, paratyphoid B vaccine, or the tetravaccine T.A.B.C., but certainly somewhat less severe, in our experience, than after using Haffkine's monovaccine. It is to be noted that occasionally one comes across individuals who show practically no reaction.

Innocuity of the Pentavaccine No. 1 (T.A.B.C.P.).

In Ceylon four coolies who volunteered were inoculated nine times each at a week's interval. They remained in good general health, though two had somewhat severe general and local reactions. All the individuals inoculated in the Balkanic and Adriatic zones (more than 400), apart from a rather severe reaction, remained in perfect health; they had each two injections—0.5 c.cm. the first time, 1 c.cm. a week later.

Blood Examination of Rabbits inoculated with Pentavaccine No. 1 (T.A.B.C.P.).

It is interesting to note that we have had much better results in rabbits inoculated in this country than in the tropics. Very often, in Ceylon, rabbits which were inoculated with more than four species of germs produced antibodies only for three or four species and not for all. In Ceylon rabbits are generally smaller than in Europe, and big healthy rabbits in this country seem to respond to inoculation much better. The results as regards agglutinins in two rabbits are collected in Table I.

TABLE I.—Pentavaccine (T.A.B.C.P.).

Porcelli observed that rabbits inoculated with the pentavaccine T.A.B.C.P., prepared by one of us, showed complete protection against the subcutaneous injection of virulent plague bacillus.

Blood Examination of Individuals Inoculated with Pentavaccine No. 1.

Lack of time has prevented the study of the amount of all protective substances produced in inoculated individuals. The investigation, therefore, has been limited to studying

the amount of agglutinins produced in comparison with individuals inoculated with simple "one disease" vaccines, the results being practically identical.

PENTAVACCINE No. 2 (T.A.B.C.M.).

This combined vaccine is prepared according to the technique already described. It is so standardized that each cubic centimetre contains:

Typhoid	500 million.
Paratyphoid A	250 "
Paratyphoid B	250 "
Cholera	2,000 "
Malta fever	2,000 "

In man $\frac{1}{2}$ c.cm. is given at the first injection, and the same or double the dose a week later.

Inoculation of Rabbits.—Three rabbits have been inoculated, with the results as regards agglutinins shown in Table II.

Inoculation in Man.

In man 0.5 c.cm. is given subcutaneously in the arm, and a week later another injection of the same or double the dose. The reaction, according to observations made by one of us in Ceylon, and by Lurie in Serbia, is not severe, and the inoculated individuals are able to resume their ordinary avocations in twenty-four to forty-eight hours. The inoculated persons develop agglutinins in large amount for typhoid, in fairly large amount for paratyphoid A and paratyphoid B, in small amount for cholera and Malta fever; the amount of agglutinins produced does not seem to be much smaller than in control individuals inoculated with monovaccines.*

HEXAVACCINE (T.A.B.C.P.M.).

This vaccine consists of an emulsion in carbolyzed salt solution (carbolic acid 0.5 per cent., salt solution 0.85 per cent.) of *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, *V. cholerae*, *B. pestis*, and *M. melitensis*. The technique of preparation is the same as that for the other multiple vaccines described above. The combined vaccine is standardized so as to contain per cubic centimetre:

<i>B. typhosus</i>	500 million.
<i>B. paratyphosus</i> A	250 "
<i>B. paratyphosus</i> B	250 "
<i>V. cholerae</i>	2,000 "
<i>B. pestis</i>	500 "
<i>M. melitensis</i>	2,000 "

In man 0.5 c.cm. is given the first time and the same or double the amount a week later.

Inoculation of Rabbits.—Rabbits have been inoculated in Ceylon and in this country, the doses varying between 0.1 and 0.5 c.cm. The rabbits in Ceylon did not respond very well to the inoculation as a rule; agglutinins in a number of cases did not develop for all the germs. In this country we have had much more satisfactory results. These are collected, as regards agglutinins, in Table III.

* For details supporting this statement the reader is referred to Dr. Lurie's paper, "Observations on Castellani's Tetravaccine and Pentavaccine," BRITISH MEDICAL JOURNAL, January 8th, 1916, p. 45.

Porcelli, carrying out experiments in the South of Europe with a hexavaccine prepared by one of us, found that bacteriolysins were produced in very satisfactory amount for all the germs. He observed also that the inoculated rabbits showed complete protection to the subcutaneous injection of virulent *B. pestis*.

Inoculation of the Hexavaccine in Man.

Six persons were inoculated in the tropics in 1913, and recently twenty persons in the Adriatic-Balkan zone. The reaction, as is the case with all vaccines containing plague, is severe; somewhat less severe, however, than after inoculating with Haffkine's plague monovaccine. The blood of two of the inoculated individuals was examined regularly during five weeks for agglutinins; they developed for typhoid in large amount; for paratyphoid A and paratyphoid B in a fairly satisfactory quantity; for cholera and Malta fever in small amount; and only a trace for plague. On the whole the production of agglutinins was similar to that observed in control individuals with monovaccines; but further researches on a much larger number of inoculated individuals will be necessary before coming to a definite general conclusion.

CONCLUSIONS.

1. The inoculation of the combined vaccines mentioned in this paper is harmless. The reaction is not severe with the exception of those containing *B. pestis*, but even simple plague monovaccines, whatever their method of preparation, give a severe reaction.

2. The mixed vaccines should be prepared by using emulsions in carbolized normal saline solution (carbolic acid 0.5 per cent., salt solution 0.85 per cent.) without heating. These emulsions give much less local reaction than broth cultures killed by heat. The presence of 0.5 per cent. carbolic acid is sufficient to kill the micro-organisms.

3. It is essential to use in the preparation of the vaccines selected strains of the various micro-organisms which have been found by experience to be rich in antigen. This is especially the case as regards *B. paratyphosus A* and *M. melitensis*, some strains of which are very poor in antigen, and when injected give rise to only a small production of antibodies.

4. Combined vaccines are of practical advantage, especially in the case of troops, rendering possible a contemporaneous immunization for several different maladies; this saves a great deal of time, and the men do not suffer the discomfort of a large number of inoculations. To protect the troops against typhoid, paratyphoid A, paratyphoid B, and cholera with the old method of ordinary monovaccines in succession, eight inoculations at least were necessary, spread over a period of two months; with the tetravaccine T.A.B.C. two inoculations only are sufficient, spread over a period of a week.

5. The triple vaccine, typhoid + paratyphoid A + paratyphoid B (T.A.B.), prepared and used by one of us since 1905, has been adopted in practically all the armies. We consider that the tetravaccine (T.A.B.C.) is also past the experimental stage, and should be adopted in the routine inoculation of troops going east. The pentavaccines (T.A.B.C.P. and T.A.B.C.M.) have given encouraging results, and can, in our opinion, be used without any risk. The hexavaccine (T.A.B.C.P.M.) is still in the experimental stage, and we propose to continue our experiments

on it, as we consider that this vaccine, if it be found efficient, would constitute the ideal vaccine for use in the tropics.

RUPTURE OF LEFT BRONCHUS FROM TRACHEA.

BY

JOHN PATRICK, M.A., M.B.GLAS., F.R.C.S.EDIN.,

F.R.F.P.S.GLAS., CAPTAIN R.A.M.C.(T.),

SURGICAL SPECIALIST, — CASUALTY CLEARING STATION, SALONICA.

WHILE there is no limit to the variety of possible injuries which the body may suffer, and while the record of them may tend to be equally limitless, occasionally a case is met with whose vagaries are so peculiar as to merit notice. I have had many opportunities of examining the bodies of persons who have died as the result of violence, but I cannot recall any injury quite like that of the following case:

Gunner J. S., aged 34, was admitted to the casualty clearing station, Salonica, with the story that he had on the previous day fallen from an empty general service limber, whose wheel had passed over his chest.

On admission he was suffering great respiratory distress, with orthopnoea. The complexion was livid, face swollen, eyes apparently bulging and lower eyelids very full. There was a great collar-like emphysematous swelling from the edges of the lower jaw to the clavicles, extending backwards across the posterior triangles. The left side of the chest was flattened, owing to fracture of several ribs. There was limited emphysema of the left side of the chest in the axillary line. The sternum was broken at the junction of the manubrium and gladiolus. There was no bruising or other evidence of injury on the skin of the chest wall. The temperature was 103.4°, pulse 110, respirations 44. No mitigation of the patient's distress and agony resulted from treatment. It was thought that his condition was due to acute pulmonary congestion with pneumo-haemothorax; he was so ill, however, that clinical examination was very imperfect. The temperature varied from 99.6° to 102°; the pulse very quickly reached from 128 to 140, and was often uncountable; the respiratory rate ranged from 40 to 52. His condition became rapidly worse, and he died seventy-two hours after injury. *Post-mortem* examination revealed the following:

1. Fracture of third to seventh left ribs at the anterior axillary line, the fifth penetrating the parietal pleura.

2. Fracture (incomplete) of the sternum at the junction of manubrium and gladiolus.

3. The left lung was collapsed to about one-fourth its ordinary size; the lower lobe was intensely haemorrhagic, with a blood cavity within it 2 in. in diameter; on section the lung appeared to be one mass of blood clot; the visceral pleura was covered by very thick shaggy exudation; there was no gross visible laceration of lung; the left pleural cavity was half full of blood.

4. Acute generalized pericarditis, exudation exceedingly loose, of buttered bread appearance; in the pericardial cavity were 1½ drachms of thin pus; heart otherwise normal.

5. Separation of the left bronchus from trachea, the tear being through the anterior portion to the extent of two-thirds of the circumference; acute inflammatory reddening of the mucous membrane of both bronchi; inflammatory infiltration of cellular tissue of middle mediastinum; the cartilaginous rings of trachea and bronchi normally flexible and tough.

The most striking primary features of the *post-mortem* examination were the profound degree of collapse of the left lung, its acute haemorrhagic state, evidence of the severity of the crushing blow, and the acuteness of the pericardial inflammation. This last was difficult to account for, and it was not till closer search was made that the rupture of the left bronchus from the trachea was found. There was no discoverable tear in the posterior pericardium,

though it was distinctly thinned. The source of infection of the pericardium seems, therefore, to have been through the great gap in the respiratory tract. From this gap also came the air which forced its way up the cellular tissue of the mediastinum within the deep cervical fascia so as to form the emphysematous collar described. The possibility of the tear at the junction of bronchus and trachea being an accident of the *post-mortem* examination may be definitely excluded. The valves at the junction of the internal jugulars and the great veins of the neck were examined and found to be intact.

If one tries to pull the bronchi apart from the trachea with the parts *in situ* within the chest cavity it will be found to be impossible. Even after removal from the body if the trachea be taken in one hand and the lung torn away from it with all one's power it will be found that the broncho-tracheal junction will not yield. The force exercised by the wheel of the limber crossing the chest without evidence of injury to skin must have been extraordinary. The wheel was thought by the man to have passed over the thorax obliquely from left to right, following a line from the left nipple to the middle of the right clavicle. This fact, and the situation of the rib fractures might indicate that the lung was crushed backwards and upwards, and the bronchus bent acutely in the same direction over the vertebral column, its comparative rigidity causing it to yield while the other constituents of the root of the lung proved sufficiently resilient. Possibly there was associated with this force a bursting action in an antero-posterior direction, the rupture being in the same line.

NOTE ON THE TREATMENT OF VINCENT'S ANGINA.

By E. EMRYS-ROBERTS, M.D.,

CAPTAIN R.A.M.C.(T.F.).

— MOBILE BACTERIOLOGICAL LABORATORY, B.E.F., FRANCE.

IN view of the widespread incidence amongst our troops on this front of affections of the throat and gums due to the fusiform bacillus and spirochaete of Vincent's angina, it may be of value to indicate a method of treatment that has met with unvarying success since its adoption in the area served by this laboratory during the last eighteen months.

The treatment consists in the local application of the following lotion. By its use the familiar gingivitis is usually cured in about six days, while the throat condition clears up altogether in from twenty-four to forty-eight hours.

Hydrogen peroxide	5V
Vinum ipecac.	50J
Glycerin	5V
Aq	ad 3viij

Vincent's angina of the throat is not only met with as a separate infection, but is very frequently associated with diphtheria. An analysis of the cases that have reached this laboratory shows that in nearly 60 per cent. of diphtheritic throats both fusiform bacilli and spirochaetes are present, while fusiform bacilli but no spirochaetes are present in a further 15 per cent.

The *rationale* of the formula was based upon the following considerations: First, that hydrogen peroxide is especially useful in loosening and cleaning up purulent exudates, and, moreover, would militate against the growth and multiplication of the anaërobic fusiform bacillus; secondly, that ipecacuanha wine might prove to have a more or less specific action upon the spirochaete; and, thirdly, that glycerin, by virtue of its hygroscopic and penetrative properties, would effectually convey the preceding ingredients into otherwise inaccessible recesses.

Whatever may be the theoretical value of these surmises, the practical issue is beyond doubt, and the consistent results obtained would appear to merit the general use of this lotion in Vincent's anginal infections.

I wish to thank Captain Mallet, L.D.S., Captain Place, L.D.S., and the many medical officers at casualty clearing stations and field ambulances who have kindly reported their results.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PERFORATING WOUND OF THE CHEST.

THE following instance of a large foreign body passing through the chest without causing death seems worthy of record. A Greek national soldier, aged 22, was admitted to a dressing station on December 6th, 1916, with gunshot wound of the left leg, and a wound in the back $\frac{1}{2}$ in. wide, near the centre of the right scapula. There was a hard lump in the epigastric region, and haemoptysis was present. On December 7th this swelling was frozen with ethyl chloride and incised. A piece of brass tubing from a shrapnel shell was extracted. It was 10.5 cm. in length, 1 cm. in diameter, and its wall was 1 mm. thick. It weighed 25 grams; one end was smoothly cut, the other jagged and bent. On December 12th the patient was moved four miles on a travois to the head quarters of the field ambulance. Haemoptysis continued till December 13th. On December 16th he was taken four miles on a travois to a casualty clearing station, which he left, almost recovered, on December 27th.

H. S. HOLLIS.

Captain R.A.M.C.(T.F.).

CASE OF TEMPORARY BLINDNESS.

SERGEANT D., aged 49 years, was admitted complaining of being unable to see; he was so blind that he had to be led to the ward.

Hearing the call of the motherland he came voluntarily from Johannesburg to rejoin his old regiment, being a time-expired N.C.O. after having served in the army for ten years. He had always been a healthy man, and never suffered from any disease which would account for his present state.

When admitted he was so blind that he was unable to see anything, not even a man standing by his bed, and mistook the window for the door. Temperature 101.2°, pulse 79, respirations 18. Nothing was to be made out on examination of chest and abdomen, and there was nothing abnormal with respect to urine; the arteries were soft, and the blood pressure normal for his age. He complained of some headache of a diffuse nature but slept fairly well. On making a careful examination of the eyes, it was found that vision was reduced to the recognition merely of hand movements. The media were clear and the fundi healthy; no thickening of the retinal arteries could be seen, nor was there any contraction in their size.

The temperature fell gradually, and at the expiration of eight days became normal. *Pari passu* with the reduction of temperature his vision began to improve, and fourteen days after admission he could see well enough to read a newspaper. As he was not feeling strong he was sent to a convalescent home, where he stayed a fortnight, and was then discharged as fit for duty.

The usual causes of blindness unconnected with visible eye changes are hysteria, uraemia, and acute retrobulbar neuritis. The case bears some resemblance to the latter, but the pupils were undilated and normal in reaction, and there was no pain on movement of the eyes, nor pain on pressure applied over the globes.

On the whole, we are disposed to think that the cause of the temporary blindness was some toxic condition of the blood which caused either anaesthesia of the rods and cones of the retina, or of the neurons of the visual centres in the cortex.

F. P. MAITLAND, Captain R.A.M.C.,

Divisional Physician;

KENNETH CAMPBELL, Captain R.A.M.C.,

Ophthalmic Surgeon.

Military Hospital, Tidworth.

ACCORDING to M. Jules Viala of the Paris Pasteur Institute the number of persons who underwent the antirabic treatment there in 1916 was 1,391. Of these 6 died of hydrophobia, giving a general death rate of 0.43 per cent. In two of the cases, however, the disease developed in the course of the treatment, and one patient died in less than fifteen days after its termination. Deduction of these leaves the following figures: Number treated, 1,388; died of hydrophobia, 3; mortality 0.21 per cent.

Revielus.

MASSAGE.

THE number of books on massage published during the last eight or nine years is legion, but the majority of them have been textbooks addressed to masseurs, and many of them, while not defining any principles, have made claims for a method which have borne the stamp of exaggeration. There has been a need for a book addressed to the medical profession, and discussing principles. We are disposed to think that Dr. MENNELL'S volume *Massage: Its Principles and Practice*,¹ will, even in this first edition, go a long way to supply the want. The author will win the confidence of medical readers from the beginning by his insistence on the doctrine that massage is only a means to an end. This may seem a very obvious doctrine, but its full appreciation implies that the prescriber has the end clearly in view, and understands the means. He must be able to instruct the masseur as to the end, and, although without skill himself in the actual manipulations, must be able to explain the way in which massage should be begun and continued, in fact, to guide its application throughout, so as to obtain steady progress. Moreover, it must be recognized that harm may be done by injudicious massage. The end of massage being the restoration of function, and the cause of the loss of function varying, the means taken for restoration must vary according to the nature, the degree, and the duration of the disability.

Dr. Mennell's introductory chapters on the general principles of massage will be read with profit by all medical men, whether their bent be towards medicine or surgery; they present the views as yet reached by a good and patient clinical observer, as the result of experience unusual in extent and of much thought on the subject. This last quality is lacking in many books on massage. The most original point in these early chapters is the insistence on the importance of what the author calls the "reflex action of massage," which is exemplified by the effect of very gentle manipulation of a recent fracture of a limb. One of the most noticeable results is the transient nature of the subsequent swelling; this the author considers is not properly attributable to any mechanical effect, for the swelling may subside with equal rapidity whether the stroking is performed towards or from the periphery. Moreover, the massage diminishes the spasm that causes the shortening and deformity. The reflex effects of massage on the arterioles are, he holds, of importance in other cases than those of recent injury. Direct mechanical pressure on the vessels does not fully explain the effects on the blood flow that may be produced by massage; but Dr. Mennell shows that the maximum effect can be obtained even in the deeper veins by a pressure lighter than is commonly used, provided that complete muscular relaxation is obtained and preserved. With regard to what is commonly called "passive movement," some interesting views are expressed. Dr. Mennell has grasped the fact that every movement of a limb involves two sets of muscles: the one must be relaxed as the other contracts. For example, for flexion of the elbow the extensors must be relaxed, and the accuracy of movement depends upon the maintenance of a proper balance between the relaxation of the one set of muscles and the contraction of the other. For what is commonly called passive movement the patient's co-operation is required, otherwise the movement will in fact be performed against contraction of the opposite set of muscles, therefore the author proposes the term "relaxed movement" to replace "passive movement." The subject is discussed in chapters on mobilization as a sequel to massage, in which directions are given for applying the principles. It is difficult in words, even with the assistance of excellent photographs such as those provided in this volume, to enable the inexperienced to perform them, but the author succeeds on the whole fairly well. All his plans are simple, as is also the machinery he uses; for re-education in walking he seems almost wholly to dispense with machinery.

The book contains chapters also on the treatment of functional disorders, of neuralgia and neuritis, and of

various constitutional conditions, as well as of diseases of the digestive, the circulatory, and the respiratory system. The concluding chapter deals with deformities, with special reference to those produced by gunshot wounds.

We have rather spoken of the book as a first essay towards a theory of a system of massage. This observation is just, because we have no doubt that the author will eventually develop his teachings further. The teachings of the book conflict with some of the most cherished notions of the masseur, but, as we have said, the book appears to us to be the best on the subject for the use of medical men; it is valuable not only for what it contains but for what it suggests.

THE PSYCHONEUROSES OF WAR.

IN their excellent handbook on the psychoneuroses of war² ROUSSY and LHERMITTE frankly state that their recent experience has enforced the truth of Babinski's views and the errors of the classical conception of hysteria; they refer to the manifestations of the war psychoneuroses almost indifferently as functional, pithiatic, or hysterical. They hold that the vast majority of psychoneurotic subjects are predisposed by heredity or personal antecedents, such as bad education or alcoholism, and in a combatant neuropath the repetition of emotional shocks induces an anaphylactic mental state for such stimuli. The directly exciting factors are concussion, local injury, emotion, and suggestion, auto-suggestion being more important than hetero-suggestion, and of the latter that exerted by medical men is more powerful than that exerted by one patient on another. The psychoneurotic symptoms do not follow immediately on the exciting shock; there is a period of incubation or meditation of variable length, and as a result few cases develop in the fighting line. Beginning with the simplest psychoneuropathic disorders—namely, the paralyses and contractures—the whole series is described, and a chapter is devoted to the purely psychical disturbances. The photographs illustrating the attitude of patients are most successful, especially those showing flexion of the trunk ("camptocormie"). The diagnosis is very clearly discussed, and in reference to the distinction between purposeful simulation and psychoneurosis the aphorism that the least experienced see the most malingering may perhaps be quoted. Treatment is on the lines practised for years by Dejerine, Dubois, and Babinski, consisting of unhesitating direction conveyed by more or less prolonged interviews and conversations, isolation, faradization, and re-education. The cure depends on the physician being the winner in this moral struggle with the patient. The use of hypnotic suggestion is sternly condemned. The volume ends with a useful bibliography of 164 articles, all published since the outbreak of the war.

Dr. EDER, who is imbued with Freud's teaching and firmly believes in the efficacy of hypnotic suggestion, has written a very readable book on *War Shock*³ or hysteria occurring in persons free from hereditary or personal psychoneurotic tendencies but with minds more responsive than normal to psychical stimuli. It is not, he contends, a new disease, but a form of hysteria in which one factor (psychical trauma) is overwhelmingly large in proportion to the other (predisposition), and differs from non-war shock in degree but not in essentials. He has utilized as material cases seen while in charge of the psychoneurological department of a military hospital at Malta. The diseases considered—hysteria and psychasthenia—are without any underlying physical basis; insanity is not included, and the term "neurasthenia" is excluded, as the author is unable to find, at any rate among the disturbances created by the war, any clinical entity that corresponds with it. His 100 cases are classified as: conversion hysteria 77, anxiety hysteria 17, and psychasthenia 6; but admittedly most of those grouped as anxiety hysteria would be regarded by Janet as psychasthenia. Out of his cases 70 per cent. were without any family or personal nervous instability, whereas in the remaining 30 per cent. there was such evidence; these results agree with those of Elliot Smith, but differ from those of Mott, Forsyth, Roussy, Lhermitte, and others. Treatment by hypnotic

² *Les psychonévroses de guerre*. Par G. Roussy et Jean Lhermitte. Collection Horizon. Précis de médecine et de chirurgie de guerre. Paris: Masson et Cie. 1917. (Pp. 184; 13 plates. Fr. 4.)

³ *War Shock*. By M. D. Eder, B.Sc., M.R.C.S., L.R.C.P. London: Heinemann, 1917. (Pp. 154. 5s.)

suggestion cured 80 and improved 14 out of 97 cases; this includes 5 cases submitted to psycho-analysis, with one cure and 4 improvements. Although he admits that the war has created some new diseases, such as trench fever, and greatly increased our knowledge of those existing, he denies that any fresh psychoneuroses have arisen since 1914, and remarks that Oppenheim's new diseases—reflex paralysis and akinesia amnestica—are the outcome of ignorance of contemporary psycho-pathological work.

We may note in this connexion a substantial volume by Dr. FRANCIS HECKEL,⁴ although it is neither based on the experience of the war nor, as its title might naturally lead the reader to suspect, is it a description of war neuroses. In fact, had it not been for the interference with printing and publishing caused by the outbreak of war, this work would have seen the light in 1914. This delay has, indeed, enabled the author to make a reference to the influence of war, but otherwise the argument is on pre-war lines, and to the effect that there is a reciprocal relation between emotional states and metabolic diseases, in that each may induce the other. He thus endeavours to detach the neurosis of terror (if this is the proper translation) from the realm of the alienist and to show its relation to general pathology and its connexion with metabolic disorders, in which he is especially interested. The term "neurosis of terror" was introduced in 1895 by Freud, with whose views the author is entirely out of sympathy. The clinical manifestations are divided into (1) psychical, almost entirely confined to emotional anomalies; (2) physical and functional disturbances of the viscera, such as spasm of the excretory and secretory ducts, false angina pectoris; and (3) metabolic disorders of very various kinds, including diabetes, gout, obesity, calculous diseases, asthma, rheumatism, migraine, eczema, urticaria, neuralgia. At first in a latent and chronic stage, the neuroses subsequently become paroxysmal. The work is laborious, but it seems doubtful if so much trouble is really necessary at the present time to show that metabolic disorders may be caused by emotional shock, and, on the other hand, that metabolic diseases may give rise to nervous and psychical disturbances.

PHYSICAL TREATMENT OF WAR DISABILITIES.

*Physical Remedies for Disabled Soldiers*⁵ is the title given by Dr. FORTESCUE FOX to the book written by himself and other authorities on methods of treatment other than those of surgical operation or the administration of drugs, vaccines, etc., thus marking the change which has taken place in the meaning of the word "physic," which is still popularly associated with the swallowing of drugs. Whether some better term might not be found for external treatment is a question, for in its broadest sense all remedies, except psychical, are physical. Be that as it may, Dr. Fortescue Fox is well qualified to describe the baths and exercises and various manifestations of electrical and radiant energy which are applied at the Red Cross clinic under his charge, as well as the climatological treatment at various health resorts. He has been well seconded by his coadjutors, Major R. Tait McKenzie, Dr. Herniman-Johnson, and Dr. James B. Mennell, and the book should prove a most valuable guide to all who are engaged in treating the deformities and disabilities following on injuries received in warfare, especially by helping them in the difficult task of choosing what form of treatment is most likely to benefit each patient.

Dr. F. P. Nunneley, of Llandrindod Wells, who has made a careful study of whirlpool baths at Brighton, states that their use at a temperature of 110° F. to 120° F. produces better results than radiant heat, and is a valuable preparative to massage. The chapter upon re-education and work is of considerable interest, and the description of what is being done on a large scale in France is not the least valuable part of it. From an economic point of view it is no use to cure a man's disabilities unless he can be made a useful citizen afterwards and not a burden upon the community.

⁴ *La névrose d'angoisse*. Par le Dr. Francis Heckel. Paris: Masson et Cie. 1917. (Pp. 535. Fr. 9.)

SURGICAL NURSING AND AFTER-TREATMENT.

Dr. H. G. RUTHERFORD DARLING's work on *Surgical Nursing and After-Treatment*⁶ has been written in accordance with the syllabus laid down for the final examination of the Australian Trained Nurses' Association. In the course of thirty-two chapters he deals first with the general principles of surgical nursing, such as the furnishing and management of an operation theatre, the preparation of patients, instruments, dressings and ligatures for operations, and with such details as vaginal douching, the administration of enemata, bandaging, catheterization, hypodermic injections, nasal feeding, making of splints, and the hundred and one other things with which a nurse should be familiar. The subjects of haemorrhage, shock, concussion, fractures, dislocations, and sprains are also discussed. Secondly, he deals with regional surgical nursing, devoting a chapter to each portion of the body, and describing in detail the management, as far as a nurse is concerned, of each operation. Preparations for the operation, arrangements during the operation, the after-treatment of the case, and the complications which may arise, are gone into minutely. A great deal more is contained in the book than would ever be left to a nurse by an English surgeon, the discussions on after-treatment especially being such as would be described in an ordinary surgical work on after-treatment intended for the use of a surgeon. Many of the important details of post-operative treatment which are and should remain the sole province of the surgeon (for example, Allingham's method of plugging the rectum for secondary haemorrhage after operation for haemorrhoids) are discussed by the author as if they were within the duties of the nurse to decide on and carry out. Possibly much of this is intended to fulfil the second term in the title, and is addressed to surgeons and house-surgeons. Certainly matters are discussed in the book which it would never fall to the lot of a nurse in this country to undertake. The book is well written, and may be recommended confidently not only to nurses (with the reservation mentioned) but also to senior students, house-surgeons, and even to the operating surgeon.

NOTES ON BOOKS.

THE twenty-sixth edition of the *Annual Charities Register and Digest*⁷—for the current year—will prove, like its predecessors, of the greatest value to all who wish for information as to agencies for the prevention and relief of distress, and for guidance in dealing with individual cases. The introduction by Sir C. S. Loch on "How to help cases of distress," again forms a valuable feature of the work, while the very full table of contents, and the elaborate index make it easy to find one's way throughout the volume in spite of the wealth of detailed information which it contains. It is an indispensable book of reference for those engaged upon organized charitable work.

⁶ *Surgical Nursing and After-Treatment*. A Handbook for Nurses and Others. By H. G. Rutherford Darling, M.D., M.S. Lond., F.R.C.S. Eng., Assistant Surgeon, South Sydney Hospital. London: J. and A. Churchill. 1917. (Cr. 8vo, pp. xii + 582; 129 figures. 8s. 6d. net.)

⁷ *The Annual Charities Register and Digest*. With an introduction by C. S. Loch. Twenty-sixth edition. London: Longmans, Green and Co., and the Charity Organization Society. 1917. (Demy 8vo, pp. 1054. 5s. net.)

THE review of Japanese periodicals by the staff of the Research Department of the Severance Union Medical College, Seoul, Korea, of which Dr. Ralph G. Mills is director (vol. 2, part ii), contains a contribution to the pathogenesis of lacquer poisoning. L. Toyama and I. Kayaba state that predisposed persons are sometimes affected on passing near a varnish tree or walking through a shop containing lacquered articles. This has been attributed to some volatile substance, but there are facts which suggest that there may be some other agency. While a house was being repaired a pot containing a hard black material, which was pronounced by an expert to be lacquer, was found. As it had been buried for centuries, it was assumed that all volatile substances had disappeared, but toxic matter was still present. The chief ingredient of lacquer is "urushiol," which is blackened from oxidation by laccase contained in the juice of the plant. Various derivatives of this substance are found in the lacquer—a hydrated and a methylated urushiol, which are also toxic, and two non-toxic forms, dimethylated and hydrodimethylated urushiol.

REMAKING THE DISABLED.

A COMPARISON of the account given this week (p. 369) of the principal military orthopaedic centres now at work with the information on the subject we were able to publish last May shows that considerable progress has been made towards perfecting the extensive organization required. The goal is to provide on a sufficiently large scale and at convenient centres the staff and equipment necessary for the systematic treatment of all men suffering from disabilities of the limbs due to injuries received in the war. This, stated in a very general way, is the aim of the department of practice to which the term "military orthopaedics" has been applied. Originally the word "orthopaedics" was framed to specify the correction of deformities in children, but it had already been extended before the war to embrace deformities produced in adults by injury or disease, and it had been recognized that methods of treatment primarily designed for children were applicable also to their elders. If, as we believe to be the case, the word was constructed, not from *παῖς*, child, but from *παιδεία*, the secondary extended meaning of which was "education," it will be found appropriate, since re-education is an important part of the treatment of men disabled by wounds. It is not, for instance, sufficient to make the movements of a stiff joint free; the muscles wasted by disease must be put in the way of recovery, and the will must be educated to use them in co-ordinated actions.

When the classes of military cases calling for orthopaedic methods of treatment are passed in review it will be found that they are numerous, and that each class includes very many wounded men. We think first of derangements and disabilities of joints including ankylosis, and of malunited and ununited fractures. We have to think also of traumatic lesions of nerves requiring a long course of treatment by splinting, massage, electricity, and often also by operation such as nerve suture or tendon transplantation. An orthopaedic centre must also be prepared to supply surgical appliances for all cases of disablement; they are best made in workshops forming part of the equipment of the centre; there the men can be properly fitted, the use of the appliances learnt, and any necessary alterations or adjustments made before discharge. In addition, the centres may be conveniently used for the correction of deformities and disabilities of the feet which interfere with a man's marching powers and general activity, such as hallux rigidus, hallux valgus, hammer-toe, metatarsalgia, flat and claw feet, and painful heels.

Compound fracture of the femur due to gunshot wound is perhaps the most serious injury of a limb that can be sustained. It is serious at the time, endangering life, owing to the frequency with which such wounds become infected, and it is serious also owing to the disabling deformity that may remain after the wounds have healed and the bones united. The course of treatment must be prolonged, but the best opinion seems to be that, given the thorough and systematic application of methods now well understood,

the majority of these cases, if the primary infection of the wound can be controlled, may be expected to recover with useful limbs without much shortening or deformity. Continuity of treatment is essential, and the limb once properly splinted must be retained in correct extension and alignment until the long process of consolidation is complete. There is probably no class of case in which treatment can so beneficially influence the final result, but it must be conducted on sound principles by the best modern methods, and must be continuous. The method of splinting adopted must be such as to enable the surgeon to treat the wound, and watch its progress without taking off the splints; the movement of the parts inevitable in the removal and readjustment of splints will not only retard consolidation but may light up quiescent infection. Considerations such as these have, we understand, caused the military authorities to prescribe that fractures of the femur are to be included among orthopaedic cases, and to be sent for treatment to orthopaedic centres, where it may be found advisable to set apart special wards for them.

The purpose of an orthopaedic centre is restoration of function, and its activities may be divided into three stages: In the first, the surgeon attends to the immobilization of fractures, removes obstacles to free movements of joints and tendons, and seeks to restore interrupted continuity of nerves. In the second, massage, electricity, and baths are used for the restoration of muscular action, and for the relief of pain and stiffness of joints. These two stages overlap; baths, for instance, may be used as a preparation for manipulative treatment of joints. The third stage is the training of the man to use his limb. A complete orthopaedic centre comprises, therefore, not only theatres for aseptic operations and for surgical manipulative treatment, and a plaster room, but also massage, electro-therapeutic, and hydrotherapeutic departments, each under skilled medical direction. To order massage, electricity, or baths without ensuring that the treatment is properly carried out with regard to the particular need of each case is to waste time and energy. The centre must possess also facilities for physical exercise, including gymnastics, and, for the final training, curative workshops where a man may resume or learn a trade. The part played by these workshops at this stage is of the highest importance not merely because through them a man may be returned to civil life, capable of doing useful work, but also because the purposive movements of, for example, carpentering or metal work call the higher centres of movement into activity, enlist the will, which is the natural stimulus of voluntary movement, and have a most beneficent effect on the mind as increasing skill is gradually gained.

In conclusion, we would suggest that larger use might be made of the great opportunities that exist in these centres for affording to surgeons instruction and clinical training in orthopaedics. If courses open to all surgeons were established at the principal orthopaedic centres in the United Kingdom there would, we believe, be no lack of applications from those anxious to obtain such post-graduate instruction and experience. The principles can be grasped by reading, but skill in their application can be most certainly and quickly attained by observation and practice of the various points of detail in manipulation, and in the making and adjustment of appliances which are so essential to success. One of the benefits surgery may hope to win out of the wreckage of war is a permanent improvement in methods of treating fractures and other injuries of the limbs and of

preventing the development of deformities and disabilities. The knowledge and experience to be gained in an orthopaedic centre is needed now for the treatment of wounded soldiers and sailors, but it will be wanted in the future in civil practice; the provision of facilities for gaining experience and dexterity now will be a lasting benefit to all practitioners, alike to those who will work in agricultural districts and to those whose lot will be cast in industrial communities.

A BIOLOGICAL CONCEPTION OF LIFE.

DR. J. S. HALDANE, in his too rare excursions into the exposition of the principles of physiology, is easily tempted into the paths of philosophical speculation, much to the profit of his hearers or readers. In 1915 he gave the course of Silliman lectures at Yale College; his subject was organism and environment as illustrated by the physiology of breathing. The course has recently been published in a volume¹ which gives a very thorough account of his own researches and of those of many others by whom our knowledge of the respiratory mechanism and its control has been advanced to its present position.

He has taken this occasion to set out once again his views as to the nature of life. Physiologists in general, as he points out, are for the most part either vitalists or mechanists when it comes to explaining what life is. The mechanistic physiologist holds that life can be explained in terms of matter and motion, in accordance with the chemical, physical, or mathematical laws known to us. The vitalist, on the other hand, holds that some obscure vital principle or force is at work in the living body to regulate the processes, chemical, physical, or what not, that result in what we all recognize as life. Looked at from another point of view, the vital principle is an influence that resists the tendencies of physical and chemical agencies to produce disintegration of the structure of the living body. Ever since the middle of last century physiologists have been for the most part mechanists or materialists, though always there has been a stout minority of vitalists to oppose them. Vitalism received a considerable impetus some time ago from the work of an experimental embryologist, Hans Driesch, who restated the evidence for the view that we must assume the existence of some guiding influence in living matter which directs development into the right way. This guiding principle or vital force he called "entelechy."

Dr. Haldane himself is emphatically neither a mechanist nor a vitalist; to judge from a footnote in the book of his lectures he might allow himself to be described as an organicist. He first gives an account of the regulation of breathing, a very complex affair of co-ordination between both chemical and nervous mechanisms, designed so as to keep the percentage of CO₂ in the pulmonary alveoli as near the figure 5.6 as may be. He then passes on to a description of the readjustments of this regulation in acclimatization and disease—here will be found an account of the curious and almost purposeful properties of oxyhaemoglobin, the oxygen-carrier of the red blood corpuscles—and then points out the importance of the acidity or alkalinity of the blood, so far as respiration is concerned. It was only recently that Hasselbalch of Copenhagen succeeded in finding a trustworthy method of determining the reaction of the blood, or rather its richness in hydrogen

ions and hydroxyl ions; Dr. Haldane shows how acutely sensitive the respiratory centre in the medulla is to changes in the alkalinity of the blood, which is itself in turn mainly dependent upon metabolic processes going on in the liver and in the kidneys, but also tends to vary from moment to moment in accordance with such variable factors, to mention one only, as the development of lactic acid in muscles that are being used. Dr. Haldane illustrates his points with examples drawn from the experience of mountain climbers, balloonists, dwellers at Pike's Peak, persons exposed to carbon monoxide fumes, and numerous experimental physiologists. The position with regard to the respiration, as with the circulation and with the other systems of the living body, may be summed up in the words used by Claude Bernard forty years ago—all the vital mechanisms, varied as they are, have only one object, that of preserving constant the conditions of life in the internal environment of the cells composing the body.

Finally, Dr. Haldane summarizes his objections to the inadequate conceptions of both mechanists and vitalists, and points to organic regulation as the essence of life. The living organism as a whole is seen to regulate its internal environment with extreme delicacy, and no less to regulate its external environment so far as it can; yet, given change in the latter, it exhibits great powers of adaptation to the altered circumstances, even changing its own structure while preserving perfectly its own identity and characteristic activities. The laws of physics and chemistry, adequate as they may be for the inanimate world, do nothing to explain the fact of organic regulation, and can give no picture of the control of the processes in the living tissues which is their most characteristic feature. This is not for want of physical or chemical data; we must conclude, then, that it is the very conceptions of matter and energy, of physical and chemical structure and changes, that are at fault when it is the organic world that has to be explained. Away, then, with the mechanists! As for the vitalists and believers in Driesch's entelechy, they ignore the participation of the environment in the regulation of the organism; vitalism does not correspond to the observed facts therefore; and as, in addition, it seems to set a limit to the experimental investigation that is essential to the progress of physiological science, it, too, must go by the board.

Physiology, says Dr. Haldane, has always dealt with life, and not with what physics and chemistry are at present capable of interpreting. He holds that each detail of organic structure, composition, and activity is a manifestation or expression of the life of the organism regarded as a separate and persistent whole. The life of an organism, including its relations to internal and external environment, is something of prime reality, since it persists actively and as a whole. What persists is neither a mere definitely bounded physical structure nor the activity of such a structure; there is no sharp line of demarcation between a living organism and its environment. An organism and its environment are one, just as the parts and activities of the organism are one, in the sense that though we can distinguish them we cannot separate them unaltered, and consequently cannot investigate or understand one apart from the rest. It is literally true of life, and no mere metaphor, that the whole is in each of the parts, and each moment of the past in each moment of the present. To the biologist, therefore, absolute space and time, matter and energy, are but partial aspects of reality; the fundamental facts with regard to life cannot be made to fit into the conceptions by means of which we now so successfully

¹ *Organism and Environment as Illustrated by the Physiology of Breathing*. By John Scott Haldane, M.D., LL.D., F.R.S. 1917. Oxford University Press: H. Milford. (Crown 8vo, pp. xii + 138. 5s. 6d. net.)

interpret inorganic phenomena. The biologist must treat life as a primary reality; materialism and vitalism, both serviceable creeds in their day and within strict limitations, are creeds outworn.

Going beyond his biological conception of life as organic regulation transcending structure and form, Dr. Haldane points out that the higher organisms are also centres of knowledge and volition, and concludes that it is unmeaning to treat consciousness as a mere accompaniment of life. Conscious personality, he says, is far more than mere organism, and the conception of life is just as inadequate in connexion with personality as are the conceptions of matter and energy in connexion with life. Biology, dealing with living organisms, has for its material an order immanent in the natural world that is far above the order disclosed to us by the study of the inorganic world. Can biology help us in the search for evidences of the presence of God in the natural world? No, says Dr. Haldane; it is not from the data of biology, and still more clearly not from those of the physical sciences, that we derive our conception of God, but from the facts of knowing and consciously doing which we observe in ourselves and our fellow men as conscious personalities. It is the perception that in us as conscious personalities a Reality manifests itself which entirely transcends our individual personalities, that constitutes our knowledge of God. It is in the world of duty and knowledge, not in the natural world as such, that we find the God whom our fathers have worshipped, and in whose strength they have been of good courage and faced trouble, danger, and death. In losing our individual lives we find our true life, and in no part of human activity is this losing of the individual self more clearly realized than in scientific work. The life of such a man as Charles Darwin is in truth a standing proof of the existence of God.

SCIENTIFIC AND INDUSTRIAL RESEARCH.

THE second annual report of the Committee of the Privy Council for Scientific and Industrial Research, which deals with the year 1916-1917,¹ has just been issued. In December last the Government decided that the work of the Committee, together with that of its Advisory Council, should be consolidated by the setting up of a separate department known as the Department for Scientific and Industrial Research, with offices in Great George Street, Westminster. The foundation of the new department led to the creation of the Imperial Trust for the Encouragement of Scientific and Industrial Research, for which purpose a Royal Charter was granted. The report of the Advisory Council records progress made in various directions. The vital need for research at the universities, especially in pure science, and for co-operation between capital, management, science and labour, is insisted upon. During the past year the council have addressed themselves in the main to the organization of industrial research; their motive for this is twofold—the paramount importance of arousing and maintaining the interest of manufacturers in the application of science to industry, and the circumstance that the war has created in industry an atmosphere favourable to the growth of new ideas. On the other hand the war has, unfortunately, made the prosecution of work in pure science, and the organization thereof, a matter of extreme difficulty. The main policy of the year has accordingly been the working out of a scheme of co-operative industrial research. It will be remembered that the Government has placed a fund of one million pounds sterling at the disposal of the department, thus enabling it to encourage the more important industries of the country to undertake research.

Realizing that the independence and initiative of British manufacturers are a great national asset, and that State help, to be effective, must aim at increasing these qualities, the Council decided that the new fund should be disbursed for the most part on a co-operative basis, in the form of liberal contributions towards the income raised by approved voluntary associations of manufacturers established for the purpose of research. Grants in aid are also made to approved individual workers engaged in sporadic investigations. Matters of direct medical interest dealt with in the report are inquiries into the hygienic effects of atmospheric pollution, and into the conditions of labour in mines. The department made a grant last November for researches into the influence of hot and moist atmosphere on miners, and into the methods of cooling and drying the atmosphere of mines, the experimental work being carried out in Dr. J. S. Haldane's laboratory in Oxford and in other suitable laboratories. A research was also undertaken by a committee appointed by the Council, with the object of producing standard types of breathing apparatus for mine rescue work. Dr. W. M. Fletcher, who is assessor to the Council from the Medical Research Committee, was given a watching brief in relation to the experiments of this committee with oxygen apparatus. The wider aspects of the work of the new department concern the medical profession. Its purely industrial features are somewhat remote from the medical sciences and medical practice; but in so far as the department stands for the organization and endowment of research as a whole, its aims and methods deserve our close attention.

EXPERIMENTS ON ANIMALS IN 1916.

THE return relating to experiments on living animals during 1916¹ has been presented by the Chief Inspector, Professor G. D. Thane, who, in view of the pressure due to the war, again submits a summary report. In England and Scotland the total number of persons who held licences during the year was 651, and of these 352 performed no experiments. Twenty-two new places, mostly laboratories connected with military hospitals or Government establishments, were registered for the performance of experiments. The report contains the usual list of licensees and the number of experiments returned by each. It is divided into two parts for the purpose of separating experiments performed without anaesthetics from those in which anaesthetics were used. The total number of experiments was 66,043, being 4,530 less than in 1915. The total is, as usual, greatly swelled by the inclusion of inoculations, hypodermic injections, and similar proceedings, which numbered 64,295. In the course of cancer investigations more than 7,600 experiments were performed by eight licensees, but were nearly all inoculations into mice; 20,000 experiments were performed for Government departments, county councils, municipal corporations, and other public health authorities; while 28,000 experiments were undertaken for the preparation and testing of antitoxic serums and vaccines, and for the testing and standardizing of drugs. During the year the several registered places were frequently visited by the inspectors, and a large number of experiments were witnessed by them. For the most part such visits were made without previous notice. The inspectors found the animals suitably lodged and well cared for, and the licensees generally attentive to the requirements of the Act and to the conditions attached to their licences by the Secretary of State. A few irregularities were noted and dealt with, one licensee having his licence revoked, and three others being admonished or censured. The report for Ireland shows that the number of persons holding licences at the end of 1916 was 20, of whom 15 performed no experiments. The number of experiments performed was 580, of which 485 were simple inoculations.

¹ Cd. 8718. H.M. Stationery Office. Price 3d.

¹ H.M. Stationery Office. Price 2d.

The inspector, Mr. R. F. Tobin, reports that he has every reason to believe that the holders of the licences obeyed the spirit as well as the letter of the Act, and that experiments were not unnecessarily multiplied.

THE USE OF SACCHARINE.

In a recent letter to the public press Dr. H. C. Ross stated that saccharine—the sale and manufacture of which he says have been prohibited in America on the grounds that as a sugar substitute it is a fraud, and that in certain doses it deranges digestion—has been shown by research in this country to be a possible predisposing cause of a serious malady of the stomach. This rather cryptic warning has incited a correspondent to inquire if there are good reasons to forbid patients the use of saccharine. The research in this country to which Dr. H. C. Ross refers is presumably that undertaken under the John Howard McFadden endowment by himself and others into cell reproduction and cancer, in the course of which it is shown that paraffin, vaseline, saccharine, and other derivatives of coal-tar act as “auxetics” or agents stimulating cell proliferation. It is in virtue of the contained auxetics that soot and tar cause squamous-celled carcinoma of the scrotum, and that kangri cancer in Kashmir is set up by contact of the soot on the braziers with the skin. But so far there does not appear to be any reliable evidence that saccharine has produced gastric carcinoma in man, or that its toxic effects are very obvious. In fact, all that Professor W. E. Dixon says in his textbook of pharmacology on this subject is that, though most coal-tar derivatives when taken continuously irritate the kidneys and cause albuminuria, it is uncertain if saccharine has this action; and in his recent work on “Food Poisoning” (p. 41, Chicago, 1917), E. O. Jordan states that in daily doses of 0.3 gram saccharine is likely to induce digestive disturbance. There does not, therefore, appear to be sufficient evidence to warn diabetics and obese patients who take saccharine in strict moderation to forego any satisfaction they may thus obtain, and we believe that the Food Committee of the Royal Society has come to a similar conclusion.

THE FUTURE OF THE MIDWIFE.

DR. E. W. HOPE, medical officer of health for the city of Liverpool, presented an interesting memorandum on the present and future position of the midwife¹ to the last annual meeting of the Association for Promoting the Training and Supply of Midwives. He pointed out that a large and increasing proportion of births among the poorer classes—nearly three quarters of the total—are attended by midwives. Many of these patients are under adverse home conditions due to want of means, which add to the responsibilities and difficulties of the midwife. Dr. Hope has long regarded the midwife as an essential factor of fundamental importance in every scheme affecting the welfare of maternity and infancy. Such a standard of midwifery skill must be provided as to safeguard the normal straightforward cases, and to recognize danger signals. The ready help of the expert must also be secured for emergencies. The author next enumerates some of the many benefits which the nation would reap from an adequate midwifery service. Thence he passes to consider the social and pecuniary status of the practising midwife throughout the country, and endorses from a wide experience the statement of Dr. Janet Lane-Claydon that in London it is hardly possible under existing circumstances for a reasonable livelihood to be earned by midwives. He admits that the State has made efforts to improve the position of these women through the Midwives Act and Orders of the Local Government Board, and through the Central Midwives Board, but more needs to be done. The real demand at the present time, he says, is for more practising midwives, all trained to the

highest plane of the present standard. Neither of these needs will be achieved unless means are found to attract a well-educated, good class of practitioner, who will be guaranteed enough pay, when trained, to free her from financial anxieties. Having argued that the midwife is essential in the present scheme of things, Dr. Hope discusses how a more efficient service may be secured by enabling a longer and better training to be taken at smaller cost to the student, and by rendering her calling less arduous and more attractive. The plan he proposes is the preliminary examination and selection of candidates, followed by subsidized training, and subsequent employment upon terms, on proof of fitness. He recommends that over and above the fee received for each patient a suitable amount should be paid. In Liverpool a fee of one guinea for emergency cases has for many years past been assured by the city council to the doctor, if the patient herself is not able to pay as much. This principle could be applied so that every midwife is assured of a fee of not less than a guinea for each birth attended. Dr. Hope claims that this arrangement would need simple administrative machinery only, and that it would solve many of the difficulties connected with the midwifery problem. A subsidized and trained midwife would be expected to undertake practice wherever she was sent; but, by the method of making up her fee to one guinea for each birth attended, her practice would be unfettered and free choice would be left to her patients; moreover, she would not be induced to shirk or undersell, her security would be greater, and she would have no bad debts. The scheme is suggestive, and seems worthy of careful consideration. The cost to the country is estimated at less than £100,000 a year.

THE PREVALENCE OF TUBERCULOSIS IN AUSTRIA.

THE increase of tuberculosis in Austria since the outbreak of the war has been the subject of several articles this year by the leading Austrian authorities on this subject. Professor R. v. Jaksch¹ writes that not only has the mortality from tuberculosis among civilians shown a most terrible rise since the second year of the war, but the figures for the army are also more disquieting. During 1915 tuberculosis was the cause of death in 18 cases (14.8 per cent.) out of 122 necropsies in reserve military hospitals in Prague. During the first quarter of 1916, when 45 necropsies were performed, death was due to tuberculosis in 9 (19.6 per cent.). In the second quarter of 1916 there were 126 necropsies, and among them death was due to tuberculosis in 40 (31.75 per cent.). Dr. A. J. Cemach² has used diagnostic subcutaneous injections of 0.004 to 0.005 gram tuberculin to demonstrate the rapid increase of tuberculosis in the army. He began to apply this test to every soldier admitted to his hospital of 100 beds in the spring of 1915, surgical as well as medical cases being included. The percentage of positive reactions was 14 to 25 in the summer of 1915, 18 to 28 in the following winter, and 22 to almost 45 in the summer of 1916. The lowering of the standard of fitness for the army was, he thought, largely responsible for this increase of positive reactions. Professor H. Schlesinger,³ in discussing the effect of the war on the character of tuberculous manifestations, says that though no form of tuberculosis unknown before the war has been seen, the relative frequency of the different forms has changed. Rapidly progressive so-called florid phthisis has become commoner, and the cervical glands oftener invaded than was the case among adults before the war. The number of tuberculous joint affections showed a rise, and, as might have been expected, gastro-intestinal complications of tuberculosis were more common than before. He agreed with other German writers that the comparative frequency

¹ *Wien. med. Woch.*, January 13th, 1917.

² *Ibid.*, January 20th, 1917.

³ *Ibid.*, January 27th, 1917.

¹ Liverpool: C. Tinling and Co., Limited, 53, Victoria Street.

of initial haemoptysis has risen during the war. On the basis of reaction to tuberculin, Professor F. Hamburger⁴ has found the incidence of latent tuberculosis among 470 soldiers between the ages 18 and 50, none of whom showed any sign of active tuberculosis, to be as high as 98 per cent. In his opinion none of the cutaneous or percutaneous methods of estimating the frequency of inactive tuberculosis with tuberculin is reliable. In sorting out the tuberculous fit for military service from the unfit he adopted the following procedure. After a fortnight's rest in bed, men who were free from fever were caused to take walks, increasing gradually from 3 to 12 kilometres, and from a leisurely stroll to normal marching speed. The men who developed fever or haemoptysis were rejected; the remainder were given three weeks' further special training, and were then drafted to the front. Discussing the perennial question whether soldier's tuberculosis is a new infection incurred in the army or the outbreak of an old infection, Professor Sörgo⁵ insists that no convincing evidence has been advanced to show that men with lungs previously perfectly sound from a clinical point of view have emerged from the war suffering from pulmonary tuberculosis. Both clinical and *post-mortem* evidence indicated that in the overwhelming majority of cases infection had occurred before the commencement of military service, but, judging by the tuberculin test, from 95 to 100 per cent. of all men in the army were already infected. He concluded that, so far, there had not been during the war any appreciable rise in the total incidence of tuberculosis, but that more inactive cases had become active than before the war; this would mean more sources of infection, to be followed eventually by a rise in the total incidence of tuberculosis.

EYESIGHT AND HEARING CERTIFICATES FOR FIREMEN IN MINES.

In a communication dated August 29th the Home Secretary draws the attention of medical practitioners in colliery districts to the provision in the Coal Mines Act, 1911, which requires that a person holding the certificate of qualification as a fireman, examiner or deputy, must subsequently, so long as he continues to be employed, obtain every five years from a school, institution, or authority approved by the Secretary of State, or from a medical practitioner, a fresh certificate in the prescribed form to the effect that his eyesight enables him to make accurate tests for inflammable gas, and that his hearing enables him to carry out his duties efficiently. For those men who obtained their original certificates in 1912, when the Act came into force, the first period of five years has now elapsed, or will shortly do so. The new certificate can only be given in the prescribed form (Mines and Quarries Form No. 73), and after applying the tests therein specified. Copies of the form and the official cards required for the eyesight test (Mines and Quarries Form No. 74 A-E) will be obtainable through any bookseller, or directly from H.M. Stationery Office. No certificate is valid unless given in the prescribed form. It is of the utmost importance for the safety of the underground workmen in the collieries that no fireman should continue to be employed as such unless his eyesight and hearing are up to the necessary standard, and the Secretary of State relies on medical practitioners to apply the prescribed tests with the greatest care and in a practical manner, with due regard to the object in view. A short explanation of the method by which firemen test for inflammable gas in mines with a safety lamp will be found in the Home Office pamphlet entitled, *How to Test for Firedamp*, price 1½d. The medical practitioner's fees for these certificates are not prescribed, but the Home Secretary has fixed the maximum fee which may be charged by an approved school, institution, or authority for the certificate at 5s.,

or, if it is a certificate as to hearing only, which is sufficient in the case of a fireman employed in a mine in which inflammable gas is unknown, at 2s. 6d. Applications for similar certificates as regards eyesight only may be made by "shot-firers" appointed under the Orders as to the use of explosives in mines. In such cases the same tests of eyesight are to be applied, and the same form is to be used subject to the necessary adaptations. For this the maximum fee chargeable by an approved school, institution, or authority is 2s. 6d.

APICAL TUBERCULOSIS IN ADULTS AND THE FOCAL TUBERCULOSIS OF CHILDREN.

OPIE¹ has made some interesting additions to his observations on the two distinct forms of tuberculous lesions which may be found in the lungs of adults. These, as quoted in a previous number of the JOURNAL (1917, vol. ii, p. 191), are (1) the apical, or that commonly recognized, which tends to spread downwards into the lung, and is not accompanied by tuberculosis of the bronchial glands, and (2) the focal or healed remains of tuberculous lesions in childhood (second to eighteenth years), which are present in at least 92 per cent. of adults, do not attack the apices more than the remainder of the lungs, being, in fact, usually found near the middle of the lung, and are accompanied by tuberculosis of the bronchial lymphatic glands. As the outcome of the present investigation, it appears that in the subjects of healed focal tuberculosis of childhood, subsequent apical tuberculosis runs a chronic course and is usually cured. Whereas in the rare cases in which an adult who has escaped tuberculous infection in childhood is attacked by apical tuberculosis, the disease may run a very severe course, and is accompanied by tuberculosis of the regional lymphatic glands. This shows the important influence of the protective vaccination exerted by the focal tuberculous lesions of childhood, and, to some extent, may explain the terrible ravages of pulmonary tuberculosis among savages when first brought under the wing of civilization. The other important conclusion is that apical tuberculosis of adults is not the result of the focal lesions of childhood but is due to a subsequent infection, for apical tuberculosis becomes increasingly frequent from adolescence to old age, or during the period when the focal lesions are completely healed, calcified, and no longer active; further, in a large proportion of the instances of associated focal and apical tuberculosis the respective lesions are in different lungs, thus rendering any spread by the lymphatic vessels improbable.

THE RELATION OF STREPTOCOCCI TO EPIDEMIC POLIOMYELITIS.

DURING 1916 several American bacteriologists reported almost simultaneously that the cause of acute epidemic poliomyelitis was a streptococcus which can be isolated from the tonsils, central nervous system, and mesenteric lymphatic glands of patients dead from the disease, and that when injected, preferably intravenously, into animals it produces flaccid paralysis. These observations of Rosenow, Mathers, Nuzum and Herzog are manifestly in opposition to Flexner and Noguchi's (1913) conclusion that the causal organism of epidemic poliomyelitis is a minute, filterable, strictly anaerobic globoid body. The results of two recent investigations are antagonistic to the view that streptococci have any etiological relation to poliomyelitis. In the first research, undertaken by Bull² at the Rockefeller Institute, streptococci cultivated from the tonsils of thirty-two human cases of poliomyelitis were inoculated into guinea-pigs, cats, dogs, rabbits, and monkeys. Streptococci cultivated from non-poliomyelitic sources

⁴ *Wien. med. Woch.*, March 10th, 1917.

⁵ *Ibid.*, April 28th, 1917.

¹ E. L. Opie: *Journ. Exper. Med.*, Baltimore, 1917, xxvi, 263-277.

² C. G. Bull, *Journ. Exper. Med.*, Baltimore, 1917, xxv, pp. 557-580.

were also similarly tested, and in both series the results were identical. In no instance was a condition induced resembling poliomyelitis either clinically or pathologically. On the other hand, a considerable proportion of the rabbits and a smaller percentage of some of the other animals developed streptococcal lesions, such as meningitis, meningo-encephalitis, arthritis, myositis, endocarditis, and cerebral and renal abscess. During the great epidemic of poliomyelitis in 1916 in New York no example of metastatic inflammation, such as usually occurs in streptococcal infection, was reported. Streptococci isolated from the poliomyelitic brain and cord of monkeys which succumbed to inoculation with the filtered virus failed to induce in monkeys any paralysis or histological changes characteristic of poliomyelitis. Further, monkeys which have recovered from infection with streptococci derived from cases of poliomyelitis are not protected from infection with the filtered virus, and their blood does not neutralize the filtered virus *in vitro*. Kolmer, Brown, and Freese,² of Philadelphia, cultivated from the cerebro-spinal fluid of cases of human poliomyelitis four varieties of micro-organisms—namely, streptococci, diplococci, diphtheroids, and Gram-negative bacilli. The first two apparently correspond to Rosenow's polymorphous streptococcus. Intracranial, intravenous, and intraperitoneal injection of these four easily cultivated micro-organisms failed to cause paralysis in rabbits or monkeys; arthritis and meningitis were produced by the streptococci, but there was no clinical or histological evidence of true poliomyelitis. The conclusion to be drawn from both these researches is that the streptococci secondarily invade the nervous system in poliomyelitis.

THE DISABLED SOLDIER IN CANADA.

In this country during the last few months placards entitled "Disabled sailors and soldiers: what every man should know" have been put up in various public places for the information of invalided soldiers and their families. A magazine entitled *Recalled to Life* has also appeared for the popular discussion of matters affecting the welfare of disabled men. The Military Hospitals Commission for Canada, whose business it is to re-establish disabled Canadian soldiers in the working world, is likewise convinced of the importance of letting every one know what must be done in order that the disabled soldier may be restored to ability and set up in a career of self-supporting industry. Hence the public, as well as the maimed soldier, must clearly understand the nature of the problem and the need for general co-operation. In addition to issuing a poster on much the same lines as the one we are familiar with, the Commission has published a miniature edition on cardboard, so that every invalided Canadian soldier may have a copy. A leaflet entitled "The Soldier's Return" is also being distributed both to disabled soldiers, and among civilians, for whose information it has in fact been mainly prepared. This takes the form of a lively dialogue, which should prove useful and stimulating to all concerned. The secretary's address is 22, Vittoria Street, Ottawa.

A CONFERENCE of representatives of Local Medical and Panel Committees throughout the country will be held under the auspices of the British Medical Association at the Connaught Rooms, Great Queen Street, London, on Thursday, October 18th, at 10 a.m. Dr. J. A. Macdonald will preside. Particulars of the business to be transacted by the conference will be published next week.

THE members of the committee appointed by the Secretary of State for War to inquire into various matters connected with the personnel and administration of the Army Medical Services in France proceeded to that country on

September 1st, and immediately began to take evidence. The Committee is instructed on its return to carry out a similar investigation in the United Kingdom.

We deeply regret to have to announce the death, on September 11th, of Dr. John Roberts Thomson, who was President of the British Medical Association when it met at Bournemouth in 1891, and afterwards for three years (1899-1901) Chairman of Council. Dr. Thomson had been in failing health for some time, though it was not generally known that his condition had become serious. We hope to publish an obituary notice in an early issue.

THE MEDICAL DEFENCE UNION.

THE annual report of the Medical Defence Union for 1916 repays study. Like all other institutions, the Union has had to contend with difficulties due to the war. A great deal of work has been cast upon the executive by the urgent claims for advice from many members in respect of their joining the R.A.M.C., and the consequent dislocation of medical practice, insurance work, and partnership agreements. Although litigation has been considerably lessened since the war began, quite the usual number of threatened actions have been dealt with. With regard to such attacks, members must feel great satisfaction in knowing that the mere fact of a letter being issued by the secretary to the person demanding compensation suffices in 98 per cent. of cases to cause collapse of the threatened proceedings; hence the wholesome respect felt by speculative solicitors for the Medical Defence Union. Passing from the work of individual defence, which has always been its first care, the Council report that collective defence of professional interests in the shape of prosecution of unqualified practitioners is carried out as a matter of policy where a case is submitted to them by public authorities or by members that successful action would benefit the public or the profession generally. This fact is recognized by the department of the Public Prosecutor, the General Medical Council, and the British Medical Association, all of which authorities have brought cases to the notice of the Council with a view to prosecution. On this matter the report makes the sound observation that the number of successful prosecutions would be greater were the Medical Act of 1858 suitably amended, as it should be, to protect qualified practice, instead of being a mere protection to certain specified medical titles, descriptions, or styles. The hope is expressed that after the war renewed endeavours to induce the State to make unqualified practice illegal may be more successful, since the trend of new legislation seems slightly in favour of this course. With regard to the National Insurance Act, it is noted that cases calling for consideration during the year were numerous, and that each fresh issue of regulations gives rise to new difficulties in panel practice. A protest is entered against the waste of time caused to overworked practitioners by inquiries held by Insurance Committees, to whom time is apparently no object, into allegations of costly prescribing for panel patients, or into frivolous and vexatious complaints by insured persons or approved societies. The solicitor's report analyses the legal work entrusted to him during the year, and contains a number of shrewd remarks on the nature of the Union's work. Since the war an increasing number of cases referred to the solicitor have concerned matters affecting the personal interests of members, particularly in regard to their partnerships or practices, or to questions arising out of the National Insurance Act. As might be expected, there is scarcely a partnership which was in existence when war was declared which has not been in some way disrupted by the calls which have had to be met by the medical profession. The guidance of the Union has been sought in many instances where the terms of partnership could not be accommodated to the new order of things. The financial report shows a sound position notwithstanding depreciations of investments, and a certain shrinkage of membership inevitable at the present time.

The annual general meeting will be held at the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1, on Thursday, September 20th, at 4.30 p.m.

THE WAR.

ORTHOPAEDIC HOSPITALS AND CURATIVE WORKSHOPS.

WE were able a few months ago (May 5th, p. 586) to give some account of the development of military orthopaedic hospitals and curative workshops, founded upon a report by King Manuel to the Joint War Committee of the British Red Cross Society and the Order of St. John of Jerusalem. We are now in a position to give particulars of further developments, founded upon another report by King Manuel.

ENGLAND.

The number of beds in the Military Orthopaedic Hospital, Shepherd's Bush, is now 1,100, but this will shortly be increased to 1,270. The total number of patients discharged from the hospital since it opened in March, 1916, is 1,737, and of these only 390 were discharged as permanently unfit, 325 were returned to duty, 507 were sent to command dépôts, and 515 to employments. The new electro-therapeutic department of this hospital, under Captain W. R. Bristow, gave over 1,600 treatments during three months, and as many cases were treated in the massage department. In the hydrotherapeutic department, opened on July 24th, an average of 79 patients are receiving treatment. At present 120 men are employed in the curative workshops and about 500 in the hospital generally. The new curative workshops which are being completed will provide places for 100 more men. The work done includes engineering, electrical work, metal grinding and polishing, felting, tailoring, fancy leather work, carpentering, photography, art iron work, oxy-acetylene welding, French polishing, painting and sign writing, metal engraving, coopering, motor-car overhauling, surgical bootmaking and repairing, and splint making. In the last named over 2,500 stock splints were made, and 339 special splints, and, in addition, numerous repairs and alterations were carried out. Of 74 men who had passed through the workshops and been discharged from hospital to August 4th, 10 had returned to duty, 35 to a command dépôt, and 20 to employments, making a total of 65 returned to the army, leaving only 9 as permanently unfit. This hospital still needs a new operating theatre, but when this has been built it will be complete.

The Military Orthopaedic Hospital at Alder Hey, near Liverpool, now has 800 beds, and is provided with massage and electro-therapeutic departments, curative workshops, and a gymnasium newly erected. It is therefore very complete, although the provision of new massage, electro-therapeutic and hydrotherapeutic departments is under consideration. It has an annexe in the Pilkington Special Hospital for Disabled Soldiers and Sailors at St. Helens, well equipped and under the medical charge of Dr. J. R. Kerr. A hospital at Calgarth, beautifully situated on Windermere lake, provided by the generosity of Mr. Hedley, is approaching completion, and will be provided with electro-therapeutic, hydrotherapeutic and massage departments, and also curative workshops. It is hoped that this may be worked as an additional annexe to the hospital at Alder Hey.

The 2nd Northern General Hospital at Beckett's Park, Leeds, provides accommodation for 800 orthopaedic patients, a number which will shortly be raised to 1,000. It is composed of huts, and has two operating theatres devoted to orthopaedic work, the one for aseptic operations, the other for surgical manipulations and the application of plaster splints. These two theatres have been built under the supervision of Sir Berkeley Moynihan and Colonel Littlewood, the officer in charge. The curative workshops are nearly finished and ready to receive the equipment provided by the Joint Committee of the British Red Cross and the Order of St. John, but new massage, electro-therapeutic and hydrotherapeutic departments, and a gymnasium are required. This hospital has already accomplished much excellent work; many cases have been fitted to return to military duty, and of the remainder the majority have been so greatly improved as to be fit to return to civil life able to use their limbs in normal fashion.

At Oxford good progress is being made with the establishment of an orthopaedic centre connected with the 3rd Southern General Hospital. Captain Girdlestone is at the

head of this centre, which will provide 250 beds in the base hospital, the Wingfield Hospital, the Radcliffe Infirmary Hut, and a hut hospital about to be built.

It has been decided also to establish an orthopaedic centre at Newcastle-on-Tyne in connexion with the 1st Northern General Hospital in the Royal Victoria Infirmary; the infirmary hopes to be able to use a large area of the town moor (Castle Leazes) for the erection of an orthopaedic department. In Newcastle also is the Cowen Home for the training of disabled men under a committee whose chairman is Sir Thomas Oliver, M.D.

SCOTLAND.

In Scotland there are three orthopaedic centres: one at Bellahouston, Glasgow, with 500 beds, under Major Parry; in its curative workshops more than one hundred men are engaged in learning various trades, and although they have only been working for a short time the results are already satisfactory. The hospital possesses a fine hydrotherapeutic department and good massage and electrical departments.

The Bangour War Hospital, Edinburgh, provides 500 beds for orthopaedic cases; the surgical work is conducted under the direction of Colonel H. J. Stiles, deputy inspector of military orthopaedics in Scotland. At this hospital a large permanent hydrotherapeutic department is being erected, but it still requires new workshops.

At Oldmill Hospital, Aberdeen, there are 500 orthopaedic beds under the supervision of Professor Marnoch. It has three large huts for use as curative workshops, and extensions are contemplated to provide more workshops, a gymnasium, and a hydrotherapeutic department.

IRELAND.

At the Military Orthopaedic Hospital, Blackrock, Dublin, there are 300 beds, with massage and electro-therapeutic departments, and workshops for carpenters, smiths, tailors, and shoemakers, and a lathe house; in addition there are six acres of land on which patients are regularly instructed in the principles and practice of horticulture. This hospital, which is under the charge of Major Potter, was opened on May 19th last; it needs additional workshops.

The Ulster Volunteer Force Hospital, Belfast, was opened on March 1st in an entirely new building situated in the grounds of the Queen's University. It is in reality a branch of the Ulster Volunteer Force Hospital, and was erected by its committee. It provides 194 beds for orthopaedic and limbless patients, but the accommodation has proved inadequate; it also stands in need of electrical, massage and hydrotherapeutic departments.

In the report the double function of curative workshops is more than once insisted upon; they are useful not only for the exercising of the injured limb and the training of the men to useful work, but also as a means of mental re-education, helping the men to a more active life, both mental and physical.

TETANUS IN HOME MILITARY HOSPITALS.

IN the JOURNAL of June 30th, 1917, was printed a summary of the third analysis of cases of tetanus treated in home military hospitals, compiled by Surgeon-General Sir David Bruce, chairman of the War Office Committee for the Study of Tetanus. We have now received from Sir David Bruce a fourth analysis of such cases, covering part of October, November, and part of December, 1916, and dealing with the first 100 cases completed since the last analysis was written. During the four periods analysed the rate of mortality has steadily gone down. In the first group the mortality was 57.7 per cent.; in the second 49.2; in the third 36.5; of the present series of 100, 69 recovered—mortality 31 per cent. The ratio of cases of tetanus to the number of wounded soldiers treated in home military hospitals was, roughly, six times as high in September, 1914, as it was two months later; and it remained at or about the lower level until the end of 1916. This fall in ratio was undoubtedly due to a great extent to the introduction of prophylactic injections of antitetanic serum, which took place about the middle of October, 1914.

The present series shows once again that the shorter the incubation period the greater the mortality rate, and vice versa. There were only twelve cases with a short incubation period (that is, up to ten days), and sixty cases with

an incubation period of more than twenty-two days; the shortest incubation period was seven days, and the longest 190. Since the beginning of the war there has been a diminution in the number of cases with short incubation periods, and a corresponding increase in the number of cases with long incubation periods. This is a measure of the action of the prophylactic inoculation of antitoxin.

Sir David Bruce points out that it is sometimes by no means easy to decide whether a case is one of localized or generalized tetanus. He defines general tetanus as that in which spasticity or rigidity occurs in muscles distant from the site of wound, trismus being the most common initial symptom in this form; in local tetanus the spasticity or rigidity is confined to the muscles in the neighbourhood of the wound. He looks on local tetanus as a much modified variety of the original disease, or even as a new type due to the action of the prophylactic injection. In general tetanus the toxin molecules may be pictured as gaining entrance to the circulation, and so reaching all parts of the nervous system. Of the 100 cases under review, 61 could be placed in the general, and 28 in the local, group; in the remainder there was doubt. In the 61 cases of generalized disease there were 21 deaths—mortality 34.4 per cent. All the cases of localized tetanus recovered. Trismus was recorded in 54 of the generalized cases, opisthotonos in 17.

With regard to operative interference, the Tetanus Committee advises that when operations are performed at the site of wounds, even if they are healed, a prophylactic injection of serum should always be given; further, they consider it probably safer to abstain from surgical interference with the wound until the ordinary treatment for tetanus has been carried out, unless there are other and imperative reasons for immediate operation. When the symptoms of the tetanus have subsided, and the tissues are flooded with antitoxin, then the wound can be opened up and searched for foreign bodies or hidden collections of pus and tetanus bacilli.

Of the 100 cases 61 were noted as having received a prophylactic injection in France; of these 51 recovered—mortality 16.4 per cent. Of the remaining 39 cases 22 were not recorded to have had prophylactic treatment, though probably many received it; of these 12 recovered—mortality 40.5 per cent. Of the remaining 17 patients who had no prophylactic injection of any kind, 6 recovered—mortality 64.7 per cent. The number of patients treated with antitetanic serum after the onset of symptoms was 98, of whom 68 recovered—mortality 30.6 per cent. Of the two cases which did not receive therapeutic treatment with serum in England, one recovered and the other died.

Once again the analysis of the cases furnishes no evidence either for or against the intrathecal route. It will be remembered that in the first year of the war the figures seemed to show that this route showed advantage over others. Analysis of the figures relating to dosage likewise furnishes no useful deduction as to the curative influence of this factor.

HONOURS.

A SUPPLEMENT to the *London Gazette* issued on September 6th contains the names of officers, non-commissioned officers, and men to whom the King has been pleased to award the Victoria Cross for acts of conspicuous bravery and devotion to duty. The name of the following medical officer, an obituary notice of whom was published in the *JOURNAL* on August 25th, 1917, appears in the list:

Temporary Captain Harold Ackroyd, M.C., M.D., late R.A.M.C. (attached Royal Berks Regiment).

For most conspicuous bravery. During recent operations Captain Ackroyd displayed the greatest gallantry and devotion to duty. Utterly regardless of danger, he worked continuously for many hours up and down and in front of the line, tending the wounded and saving the lives of officers and men. In so doing he had to move across the open under heavy machine-gun, rifle, and shell fire. He carried a wounded officer to a place of safety under very heavy fire. On another occasion he went some way in front of our advanced line and brought in a wounded man under continuous sniping and machine-gun fire. His heroism was the means of saving many lives, and provided a magnificent example of courage, cheerfulness, and determination to the fighting men in whose midst he was carrying out his splendid work. This gallant officer has since been killed in action.

FOREIGN HONOURS.

The King has granted permission to wear the following decorations conferred by the Russian Government upon medical men in recognition of services rendered to the Russian

sick and wounded under the auspices of the British Red Cross Society and the Order of St. John of Jerusalem in England:

Order of St. Anne, Class 2, with Swords.—Dr. F. G. Clemow, C.M.G.

Order of St. Stanislas, Class 2.—Dr. E. M. Hime.

Order of St. Anne, Class 3.—Mr. A. E. Hind, F.R.C.S.

A supplement to the *London Gazette*, dated August 31st, contains a further list of decorations and medals awarded by the Allied Powers at various dates to the British Forces for distinguished service during the course of the campaign; the list includes the following medical officers:

By the President of the French Republic.

Légion d'Honneur.—Croix de Chevalier: Major (temporary) Lieut.-Colonel Arthur Brownfield Fry, I.M.S.

Croix de Guerre.—Captain Lionel Douglas Bailey, R.A.M.C.; temporary Lieutenant Ratenshaw Nariman Kapadia, M.B., I.M.S.; Captain Frederick William Hay, M.B., I.M.S.; Captain James Burne Lapsley, M.B., F.R.C.S., I.M.S.; temporary Major Thomas Malcolm Russell Leonard, West African Medical Service, attached Nigerian Contingent.

It is announced that the French President has also conferred the Legion of Honour upon Dr. Frances Ivens, Surgeon in Charge of the Scottish Women's Hospital at Royaumont.

By the King of Italy.

Silver Medal for Military Valour.—Captain Charles Aubrey Godson, I.M.S.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Lost at Sea.

COLONEL T. DALY, C.M.G., R.A.M.C.

Colonel Thomas Daly, C.M.G., R.A.M.C., was reported as drowned, in the list of casualties published on August 30th. He was lost in the transport *Areadian*, when that vessel was torpedoed and sunk in the Mediterranean on the way to Egypt, on April 15th last. He was educated in Dublin, and took the L.R.C.S.I. and L.R.C.P.I. in 1882. Entering the army as surgeon on August 1st, 1885, he became surgeon-major on August 1st, 1897, lieutenant-colonel on August 1st, 1905, and colonel on March 1st, 1915. He served on the North-West frontier of India, in the Tirah campaign of 1897-98, receiving the medal with a clasp; and in South Africa from 1899 to 1902, taking part in the operations in the Orange Free State, including the action at Bethlehem, in the Transvaal, and in Cape Colony, and received the Queen's medal with three clasps and the King's medal with two clasps. He joined the Expeditionary Force in France in December, 1914, was mentioned in dispatches in the *London Gazette* of November 13th, 1916, and received the C.M.G. on January 1st, 1917. From June 14th, 1915, he had been serving as A.D.M.S. with a division of the new army.

Killed.

STAFF NURSE NELLIE SPINDLER.

Staff Nurse Nellie Spindler, Queen Alexandra's Imperial Military Nursing Service Reserve, was reported as killed, in the casualty list published on August 31st. Before the war she was a member of the staff of Leeds Workhouse Infirmary. After joining the army, she served for a time at Lichfield, and went to France in June, 1916. She was killed by a shell.

Died on Service.

CAPTAIN H. Y. C. TAYLOR, R.A.M.C.

Captain Henry Young Cameron Taylor, R.A.M.C., died at Bexhill on August 25th. He was educated at Edinburgh University, where he graduated as M.B. and C.M. in 1896, also taking the F.R.C.S. Edin. in 1905. After filling the posts of clinical assistant at the Golden Square Throat Hospital and at the Central London Ophthalmic Hospital, of house-surgeon to the Hospital for Sick Children, Great Ormond Street, and of senior house-surgeon at Huddersfield Infirmary, he served as a civil surgeon in the South African war, gaining the medal. On his return he went into practice at Bexhill, where he was medical officer of the post office and of the local branch of the British Red Cross Society. After taking a temporary commission in the R.A.M.C. he was employed at Netley Hospital.

CAPTAIN A. TRAILL, R.A.M.C.

Captain Anthony Traill, R.A.M.C. (temporary), died at a casualty clearing station, of internal haemorrhage, on August 25th, aged 27. He was the son of Edmund B. Traill

of Pebmarsh, Essex, and of Chiru, Traill, Argentina. He took the L.M.S.A. in 1915, and joined the army soon after.

Accidentally Killed.

CAPTAIN W. J. ANDERSON.

Captain W. J. Anderson, East African Medical Service, was reported as killed by accident in the casualty list published on September 10th.

Died of Wounds.

CAPTAIN J. H. BAMPION, R.A.M.C.

Captain James Henry Bampton, R.A.M.C., was reported as having died of wounds, in the casualty list published on September 6th. He was educated at Birmingham University, where he gained the Walter Myers Scholarship, and graduated as B.Sc. in 1908, and M.B. and Ch.B. in 1911; afterwards studying at Berne University. After acting as house-surgeon of Birmingham General Hospital, he took up the part of assistant school medical officer of that city, and settled at Gravelly Hill, Birmingham. He took a temporary commission as lieutenant in the R.A.M.C. on February 1st, 1915, was promoted to captain on completion of a year's service, and was attached to the Royal Field Artillery when wounded.

CAPTAIN J. E. S. WILSON, M.C., R.A.M.C.

Captain James Ernest Studholme Wilson, M.C., R.A.M.C., attached Oxford and Bucks Light Infantry, died of wounds in hospital abroad on August 23rd. He was the elder son of the late Rev. Studholme Wilson, of Stoneleigh, Newport, Salop, and was educated at the London Hospital. After taking the M.R.C.S. and L.R.C.P. Lond. in 1911, he went into practice at Iwer, Buckinghamshire, where he was medical officer of the Iwer, Denham, and Langley Cottage Hospital, and of the Alexandra House Home for Feeble-minded Girls. He took a temporary commission as lieutenant in the R.A.M.C. in the latter half of 1915, was promoted to captain after a year's service, and received the Military Cross on September 22nd, 1916.

Wounded.

Lieut.-Colonel A. S. Donaldson, Canadian A.M.C.

Lieut.-Colonel G. S. Williamson, R.A.M.C. (T.F.).

Captain E. G. Anderson, R.A.M.C. (temporary).

Captain R. S. Aspinall, R.A.M.C. (temporary).

Captain L. Ball, R.A.M.C. (T.F.).

Captain K. Biggs, R.A.M.C. (S.R.).

Captain J. E. Bloomer, Canadian A.M.C.

Captain H. M. Clarke, R.A.M.C. (T.F.).

Captain A. L. E. F. Coleman, R.A.M.C. (temporary).

Captain W. H. Cornelius, R.A.M.C. (S.R.).

Captain H. J. De Brent, R.A.M.C. (temporary).

Captain H. H. Elliot, R.A.M.C. (temporary).

Captain A. R. Hargreaves, R.A.M.C. (temporary).

Captain H. G. Janion, M.C., R.A.M.C. (temporary).

Captain J. H. Jones, Canadian A.M.C.

Captain R. W. Kenny, M.C., Canadian A.M.C.

Captain D. Lees, R.A.M.C. (temporary).

Captain W. Leslie, M.C., R.A.M.C. (temporary).

Captain W. B. Loveless, R.A.M.C. (temporary).

Captain R. D. Mackenzie, Canadian A.M.C.

Captain J. A. V. Mathews, R.A.M.C. (temporary).

Captain A. W. Matthew, R.A.M.C. (temporary).

Captain S. S. Meigham, R.A.M.C. (T.F.).

Captain T. M. Miller, R.A.M.C. (S.R.).

Captain J. Moore, Canadian A.M.C.

Captain S. A. W. Munro, R.A.M.C. (temporary).

Captain D. S. Robertson, R.A.M.C. (temporary).

Captain J. R. Small, R.A.M.C. (temporary).

Captain E. S. Smallpage, Australian A.M.C.

Captain W. Stobie, R.A.M.C. (T.F.).

Lieutenant R. T. Worthington, R.A.M.C. (temporary).

Staff Nurse E. McQuillan, Q.A.I.M.N.S. Reserve.

Staff Nurse I. Webster, Q.A.I.M.N.S. Reserve.

Prisoners of War.

Captain E. D. F. Hayes, R.A.M.C. (temporary).

Captain H. K. Ward, M.C., R.A.M.C. (S.R.).

Erroneously Reported Wounded.

Major J. P. Kenny, Australian A.M.C., reported as wounded in the casualty list published on August 27th,

was reported as *not* wounded in that of September 4th, the first report having been made in error.

Erratum.

In the obituary notice of Captain Joseph Cecil Harris, in the JOURNAL of August 25th, there was an inaccuracy with reference to his military status and service. Captain Harris belonged to the Territorial Force, and received his first commission on October 1st, 1912; he was promoted captain on April 4th, 1915, whilst serving in the 3rd North Midland Field Ambulance, with which unit he went to France in March, 1915. He was lent to a casualty clearing station for temporary duty, and was killed on August 16th by a bomb dropped from an enemy aeroplane. The same clearing station was heavily shelled throughout the following day.

DEATHS AMONG SONS OF MEDICAL MEN.

Adam, Arthur Innes, Lieutenant (acting Captain) Cambridge-shire Regiment, younger son of the late Dr. James Adam, of Emmanuel College, Cambridge, reported as wounded and missing on September 16th, 1916, now presumed killed on that date, aged 22. He was educated at Winchester and at Balliol College, Oxford, gaining a scholarship at both school and college, and served at Oxford in the cavalry squadron of the O.T.C. He took a first class in Classical Honour Moderations in 1914. He got a commission on October 8th, 1914, went to the front in June, 1915, was wounded in the following month, and was promoted to acting captain from January, 1916.

Allinson, C. H., Second Lieutenant (acting Captain) Suffolk Regiment, younger son of Captain A. A. Allinson, I.S.M.D., Bengal (retired), reported missing November 13th, 1916, now presumed killed on that date.

Beckingsale, John Edgar, Second Lieutenant, Duke of Cornwall's Light Infantry, only son of D. L. Beckingsale, M.D., of Towyn, Merioneth, killed while leading his platoon into action, August 22nd. He was formerly living in Southern California, and came home to join the army.

Bow, John Mackenzie, W.S., Private, Canadian Forces, son of the late Deputy Surgeon-General John Campbell Bow, I.M.S., killed August 15th, aged 54.

Burton, Arthur Vivian, Captain Royal Flying Corps, only son of Lieutenant-Colonel A. H. Burton, late R.A.M.C., killed in a flying accident at Catterick, August 30th, aged 22. He got his first commission in the Army Service Corps on December 28th, 1914, joined the R.F.C. in 1916, and was gazetted Captain in June, 1917.

Claremont, Frederick Victor Leszynski, 2nd Lieutenant R.G.A., killed in France on August 4th, 1917, younger son of the late C. C. Claremont, M.D., B.S., of Southsea, Physician to the Royal Portsmouth, Portsea, and Gosport Hospital, and of Mrs. Claremont, 81, Camden Road, N.W.

Forbes, Alec, Captain Royal Warwickshire Regiment, elder son of the late Dr. W. G. Forbes, of Stokesley, Yorkshire, reported wounded and missing on September 3rd, 1916, now presumed killed on that date, aged 28.

Hull, Edward Cecil Gordon, Second Lieutenant Royal Field Artillery, elder son of Dr. Hull, of Streatham, London, S.W., killed August 26th.

Oakshott, William Albert Neville, Lieutenant Royal Irish Rifles, only son of Dr. J. A. Oakshott, District Asylum, Waterford, killed August 16th, 1917. He was a medical student at Trinity College, Dublin, when the war broke out. He got his first commission in the Royal Munster Fusiliers on October 20th, 1914, and had been wounded in April, 1916.

O'Connor, Hubert, M.C., Captain King's Shropshire Light Infantry, eldest son of Mr. Charles O'Connor, F.R.C.S.I., died on August 17th, aged 30, of wounds received the previous day. He was educated at Clongowes Wood, the Irish Jesuit College, and at Trinity College, Dublin, where he took his degree, being afterwards called to the Irish Bar. In 1910 he contested East Limerick as an Independent Nationalist, in the interests of Mr. W. O'Brien. He got his first commission on January 6th, 1915, and received the Military Cross on June 28th, 1916.

Osler, Edward Revere, only son of Sir William Osler, Bt., of Oxford, died of wounds on August 30th, aged 21. He was educated at Winchester and Oxford, where he was a commoner of Christchurch, and received his commission in May, 1916. By his death the baronetcy bestowed on his father is left without an heir.

Price, George Bernard Locking, Second Lieutenant Gordon Highlanders, only son of the late Lieut.-Colonel William Locking Price, I.M.S., killed August 22nd. He got his commission last March.

Tudsbury, Lancelot, Second Lieutenant Royal Field Artillery, youngest son of Dr. Tudsbury, of 100, St. George's Square, S.W., killed August 22nd, aged 19.

Warburton, Arthur John Egerton, London Regiment, son of the late Dr. Arthur Warburton, of East Molesey, died of pneumonia on active service on August 14th, aged 22.

Woodforde, Major Phillip Sidney Soanne, 1st Infantry Battalion, Australian Imperial Force, somewhere in France, on May 6th, 1917, of wounds, aged 23 years. Eldest son of the late Dr. Ernest Woodforde, he was a New South Wales native, and was present at the Gallipoli landing as lieutenant, where he was wounded the first day. He returned to the peninsula, and after the evacuation was sent on to France, where he won his

way to the majority of his battalion. He was again badly wounded, sent to England, and got back in time for Pozières. Finally killed at, or somewhere near, Bullecourt.

Yelf, James Harbidge, Private, Canadian Infantry, youngest son of the late Dr. L. K. Yelf, of Moreton-in-Marsh, killed August 21st, aged 35.

Dr. L. A. Francis, of Uxbridge, writes to inform us that the good news has reached him that his son, Second Lieutenant W. F. Francis, who had been officially reported killed and of whom a brief obituary notice appeared in this column, is a wounded prisoner in Germany.

MEDICAL STUDENTS.

Barry, William Roche Brereton, Second Lieutenant Royal Dublin Fusiliers, reported wounded and missing since August 16th, 1916, is the second son of Judge Brereton Barry, of Glengageary, co. Dublin. He was a second year medical student at Trinity College, Dublin, when he got his commission in February, 1916.

Hatte, Edward Stokes, Second Lieutenant Royal Irish Rifles, killed recently, was for two years a medical student at Dublin University. He was the son of Mr. W. M. Hatte, of Kington, Cowper Road, Dublin. After leaving college he went to Ceylon as a planter, and went to Egypt with the Ceylon Planters Corps, serving in the fight with the Turks on the Suez Canal, and at Gallipoli from the first landing to the evacuation. He went to France in March, 1916, and soon after got a commission in the Royal Irish Rifles, was severely wounded in September, 1916, and rejoined in May, 1917.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

Scotland.

HOSPITALS FOR DISABLED SOLDIERS.

IN Edinburgh it has been decided to found three new hospitals for the care of discharged soldiers suffering from special diseases and disabilities caused by war service. The Edinburgh and South-Eastern District Pensions Committee, one of the four Scottish districts set up by the Ministry of Pensions, has in hand plans for the conversion of Craig End, Liberton, into a hospital for neurasthenia. At Muriston, near Calder, the Committee intend to set up a hospital for epileptics on the colony system. For orthopaedic cases a building in Edinburgh has been secured in the neighbourhood of an existing institution for technical instruction. The cost of these undertakings is being borne partly by the Treasury and partly by the Red Cross Society.

SANITARY CONGRESS AT GLASGOW.

The forty-third annual congress of the Incorporated Sanitary Association of Scotland was held on September 5th and 6th in the Masonic Hall, Glasgow. The subject of a proposed Ministry of Health was introduced early in the session, and was discussed at some length. The general principle of the setting up of such a central department was approved, but the view was expressed that Scotland should have its own head quarters. The president of the congress, Mr. F. G. Holmes, C.E., delivered his address on the practical application of modern sanitation. A brisk discussion took place on the question of the sterilization of the flesh of tuberculous carcasses, from the hygienic and economic standpoints. Mr. A. M. Trotter maintained that tuberculous meat adequately cooked by steam under pressure could be rendered harmless to the consumer, but the selection, preparation, sterilization, and distribution ought to be supervised and controlled by an official of the local authority or of the Government. In Glasgow sterilization of tuberculous flesh would provide meat sufficient for two million meals per annum. Professor Sims Woodhead and Professor Matthew Hay wrote in support of these views. Professor Noel Paton, in a letter, said that if bacteriologists found that the process of sterilization killed the bacilli it was manifest that the flesh should be used as food, especially at the present time. Professor Hunter Stewart also wrote concurring in Mr. Trotter's views, and Professor Glaister and Dr. C. Templeman, M.O.H. for Dundee, spoke to the same effect. Dr. A. K. Chalmers, M.O.H. for Glasgow City, opposed the sale of sterilized meat. On the second day of the congress the housing problem was the main topic of discussion.

Ireland.

BENEFIT SOCIETIES AND DISABLED SOLDIERS.

DR. MAGUIRE, of the Irish Insurance Commission, has awarded two soldiers, discharged as unfit for service from the army, the balances of money claimed by them in sickness and disablement insurance benefits from the Irish Trade and Labour Society, Enniscorthy, of which they were members. The society had refused to continue the payment of benefits on the grounds that the army authorities had decided that the two men were only entitled to partial disablement pensions, and were not incapable of doing light work. It was contended on behalf of the men that, while not incapable of doing certain classes of work, they were still unfitted, as the result of the injuries they received in the war, to undertake the work of farm labourers, upon which they had been engaged before joining the army.

LOCAL GOVERNMENT BOARD AND DOCTORS OF MILITARY AGE.

In reply to a communication from the North Dublin guardians, to the effect that the Local Government Board refused to sanction the appointments of Drs. Lowe and Curran to act during the absence of Drs. Donnelly and Dolan, on vacation, on the ground that the gentlemen in question are eligible for military service, Mr. T. G. Green, the guardians' solicitor, quoted orders showing that the appointment of substitutes is subject to the approval of, and revocation by, the Local Government Board, who have vested in them the power of veto; and expressed the opinion that the guardians would not be well advised to test the validity of the Local Government Board's refusal to sanction the appointments made, as, undoubtedly, the courts would hold that the Local Government Board were within their rights and powers in exercising their veto. As there had been no legal decision on that particular point the guardians might, if they wished, submit a case to counsel on it.

Correspondence.

THE ORGANIZATION OF MILITARY X-RAY WORK.

SIR,—I have before me the July number of the *American Journal of Roentgenology*. It contains a statement on the action of the U.S.A. military authorities in the organization of x-ray work for army purposes. As this is in such striking contrast to the methods adopted in this country, I venture to call your attention to it.

On June 11th the Surgeon-General convened a meeting of prominent radiologists with some of his medical officers. This conference sat in session for two weeks. As a result—

1. A number of schools for the teaching of military radiographic work were established in charge of experts in different parts of the country, and were directly controlled by the Surgeon-General.

2. Medical officers intending to do x-ray work have to attend for three months' instruction, and then are accepted or declined according to the ability shown.

3. Arrangements for the x-ray examination of recruits—especially from the point of view of the condition of the chest—were made.

4. The numerous methods for the localization of foreign bodies were considered, and it was decided that three methods should be taught thoroughly, and only these three.

The Government is defraying the expense of this organization and teaching, and officers taking the course of instruction draw, during this period, the pay of their respective ranks.

This action of the American authorities in their recognition of the importance of expert medical men controlling the radiographic work shows great foresight.—I am, etc.,

C. THURSTAN HOLLAND,
President of the Röntgen Society of London.

Liverpool, Sept. 1st.

A NEW SCHOOL FOR THE STUDY OF HEART DISEASE.

SIR,—The question of a new school for the study of heart disease is not sufficiently answered by your correspondents Dr. Poynton, Sir James Mackenzie, and Dr. Chalmers Watson. Dr. Poynton says in the *JOURNAL* for August 25th, "What we want is an institution concerned with the organization of a broad investigation of this study," etc. One of the most important and one of the most neglected methods is ignored or overlooked altogether by all three gentlemen. I refer to the radiological examination of the heart. To see a thing and observe its working is much more convincing than anything else. Progress in this direction has been largely retarded by the want of familiarity of physicians with its technique and by the modesty of the radiologists in not pressing its claims. This method cannot solve all the problems or vagaries of pathological conditions of the heart. But as a sequel to clinical examination it comes before everything else. Its advantages are obvious. To a trained observer its deductions are most definite. No method for the examination of the grosser conditions of heart disease is so precise in the information obtained. By screen examination the size, shape, conditions of hypertrophy, of dilatation, of effusion into the pericardium, of enlargement of the ventricles and auricles, dilatation of the aorta, aneurysms, and many other things are so readily seen that one sometimes marvels that they are not always cleared up in this way before attempting a diagnosis.

From these appearances the conditions of the valves can sometimes also be deduced. But without considering the latter the former are of sufficient importance to suggest, in many cases, the necessary form of treatment. Again, the appearance of the heart can now be so readily transferred to photographic paper by a single flash exposure in one 300th of a second (not the so-called instantaneous exposure which is from one-tenth to a second) that accurate study of the appearances can be made at leisure. I should place the order of a complete examination of a case of suspected heart disease in the following manner. First, clinical examination; second, radiological examination; third, cardiographic and allied methods.

No new school of heart disease in my opinion is complete without the inclusion of the radiological method.—I am, etc.,

London, W., Sept. 3rd.

JAMES METCALFE.

SIR,—Dr. Poynton's two letters on "a new school for the study of heart disease" are of such importance that I do not think any apology is needed for reopening the subject.

Dr. Chalmers Watson very pertinently asks why "heart disease" is selected as the realm of medicine in which a new school is specially required, and suggests that the study of "intestinal disorders" has a much greater claim. May I ask, Why not both conditions? And why not special schools for half a dozen of the most important diseases from which the nation suffers?

Is not the solution of this problem a ministry of health and a national medical service? Is it not possible for an efficient Ministry of Health to establish "schools of research" to study all the most important diseases? These schools of research should be in touch with all the hospitals and general practitioners in the kingdom, which would enable them to obtain from these sources the information they require.

Sir James Mackenzie has recently been advocating the carrying out of research work on "the first symptoms of disease" by general practitioners. He very rightly insists that this important work must first be done before we are able to recognize and treat disease in its earliest stages.

Advance by the single-handed effort of busy practitioners will be very slow and uncertain. But link up the efforts of every practitioner and hospital with schools for special research by means of a sympathetic and intelligent Ministry of Health, then advance will be both rapid and sure.

Does not a scheme of this magnitude thrill the imagination of all who wish to see the advance of medicine? Is not saving life and improvement of the physique of the rising generation, by a scientific study of prevention of disease and the recognition and treatment of disease in its earliest stages before irreparable organic disease sets in, the greatest service that can be rendered to the nation after

this devastating war? Will not such an improvement in the physical condition of the rising generation result in an enormous increase of national human energy and efficiency, and a corresponding increase in the breadth of the national mental outlook upon life?

I believe it is a vast scheme of this kind which Dr. Poynton had in mind when he wrote his first letter on "a new school for the study of heart diseases"; but he is rather less ambitious or rather more cautious than I am, and preferred to test his scheme on a limited semi-private basis, whilst I should like to see it begun on a broad national basis.—I am, etc.,

H. L. FLINT,
Captain R.A.M.C.

B.E.F., France, Sept. 4th.

CANADIAN UNIVERSITY HOSPITAL UNITS.

SIR,—In your issue of August 25th, on page 271, your Canadian correspondent, under the heading, "University Hospital Units," writes: "Soon after the commencement of the war the universities of McGill, Toronto, Queen's, Laval, Dalhousie, St. Francis Xavier, and the Western University, and the universities of Alberta and Manitoba, offered to the military authorities hospital units fully equipped and composed for the most part of members of each university for service overseas in whatever field they could be of most use. The offers of the last two universities mentioned (Alberta and Manitoba) were not accepted, but units have been mobilized, equipped, and sent across the seas by each of the other universities."

May I point out that after the offer of the University of Manitoba to the Department of Militia, Ottawa, to raise and equip a hospital unit had been declined, the Manitoba Medical College, which is the medical school of the University of Manitoba, offered to organize any hospital unit the Department of Militia might require. The department asked this college, through the university, to organize a casualty clearing station, and within a month from the date the authority to raise No. 4 Canadian Casualty Clearing Station had been given this unit, organized by Manitoba Medical College, was on the ocean and bound for England. It travelled on the same ship as the hospital unit from St. Francis Xavier, No. 9 Canadian Stationary Hospital, and reached England in June, 1916, about a month in advance of the unit from Western University, London, Ontario, No. 10 Canadian Stationary Hospital.

I may also add that the universities of the four western provinces—Manitoba, Saskatchewan, Alberta, and British Columbia—in addition to raising a university battalion, raised the 11th Field Ambulance, which has been continuously with the Canadian Division in France for a period of over a year.

I should not have written had I not felt that your correspondent, who usually reports very accurately medical affairs in Canada, had in this instance failed to render justice to the part played in this war by the Canadian universities west of the Great Lakes.—I am, etc.,

ROSS MITCHELL,
Captain C.A.M.C.

B.E.F., France, Sept. 3rd.

THE ASSOCIATION AND THE PROFESSION.

SIR,—Your correspondents Captain H. B. Morgan and Dr. J. A. Bell may, I think, be answered together, for though they write about different subjects, their attacks on the Association are made from the same standpoint, and are couched in much the same forceful language. This evidence of vigorous interest is refreshing and welcome, but the criticisms would be more valuable if they were not based upon an apparently complete misunderstanding of what is proposed, and a seriously imperfect knowledge of the situation which gave rise to the proposals.

Captain Morgan regards the proposals concerning a Ministry of Health, made by the Council and endorsed by the Representative Body with great unanimity, as an "outrage" "of the Prussian type," and equivalent to "burglary" and "embezzlement." This is severe, but I should like to ask him specifically which of the twenty-three resolutions he regards as partaking of this character. Some of these are practically identical with, all of them are based upon, and none of them is incompatible with, resolutions passed by the Representative Body before the war with no serious opposition to them being

evidenced either at the time or afterwards. They are not poisonous emanations from the brain of a wicked Council. They are intended to be exactly what Captain Morgan wants—a contribution to “a preliminary discussion of a scheme for establishing a Ministry” of Health, and were designed not to “force the establishment of a medical bureaucracy on the State,” but directly to prevent the establishment of such a bureaucracy by the State. It appeared to us that this would be the ultimate effect of that threatened “special legislation dealing with infantile mortality” which Captain Morgan thinks “little can be said against.” The action of the Council has at least delayed—we may hope prevented—this, and so saved the practices of our colleagues who are absent from a very serious attack.

Captain Morgan tells us that he has devoted years to the study of this question, and that a scheme of his has been submitted to the Government. I wonder if the grievance is that the Association's scheme, so far as it has been formulated in these general resolutions, differs from his own; if so, it need not be one, for I feel sure that the Chairman of the Council would be delighted to receive this scheme for submission to his committee, and I know that some of us who have been trying to help in this matter would sincerely welcome any ideas that would shed light on a peculiarly difficult subject.

Similarly, Dr. Bell entirely misreads both the nature and the intention of the proposals with regard to the treatment of discharged disabled sailors and soldiers. They are not due to the innate wickedness of the Council, but are the outcome of specific resolutions of the last conference of Panel Committees. They do not provide that these men “shall be attended under the same regulations as those at present applying to temporary residents”; they are entirely different; but they do involve the sending in of a bill before the money is paid. This apparently is the hardship for the prevention of which Dr. Bell desires to start a new organization. The proposals have nothing to do with the general question of what is proper remuneration for insurance practice, but have been separated from this question by the direct instruction of Panel Committees. The “diplomatic steps” by which they have been arrived at are quite incorrectly stated by Dr. Bell. They were much more laborious, namely, (1) persuading the Commissioners that there was a case for increased payment for these cases at all; (2) persuading the Treasury to the same effect; (3) negotiating with the Commissioners, and through them with the Treasury, as to the details and conditions of increased payment; (4) the formal submission by the Commissioners of proposals based upon the result of these negotiations; (5) the conditional and experimental acceptance of these proposals by the Insurance Acts Committee; (6) the submission of the actual draft regulations for the observations of the Committee; (7) the issue of the regulations by the Commissioners, and of a letter from the Committee recommending the Panel Committees to accept them.

Now, here again, what is the specific point to which Dr. Bell offers such vehement objection? Apparently it is that payment is to be on an attendance basis, whereas he wishes it to be a capitation fee of 10s. This was actually one of the suggestions made by the Committee, but being asked by the Treasury for data on which this particular figure could be justified, we were bound to admit that there were no such data at present, and that the figure was really a guess which we believed might be satisfactory to practitioners. The experimental period of payment by attendance is for the purpose of enabling us to get data for proper calculation. However, Dr. Bell is apparently in possession of such data already. He would do the profession and the Association a signal service if he will forward the figures to the Council or Committee. Can he prove that 10s. is the right amount rather than 8s. 6d., 9s., or even 11s.? Or does he really wish the profession to maintain as a principle that the Treasury must pay it on a guess?

Dr. Bell “calls on every practitioner in the country, whether on the panel or not, to say that he will accept” a 10s. capitation fee, and that “on no other terms will he accept any responsibility for attendance on these poor fellows.” Well, the Association hopes to do better than this. It proposes to prove its case, and if supported by Panel Committees, to ask for a 10s. capitation fee not for

disabled soldiers only, as Dr. Bell wishes, but for *all* insured persons whoever they may be. Will Dr. Bell help?—I am, etc.,

London, N., Sept. 4th.

H. B. BRACKENBURY.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

SIR,—In any comments on “Medical Benefit of Invalidated Seamen, Marines, and Soldiers” (Memorandum 234 I.C., and also on 233 I.C.) I hope it will be pointed out very plainly and distinctly that the remuneration is the *dividend* rate (233 I.C., par. 7, lines 7, 8, and 9; and 234 I.C., par. 5, lines 7, 8 and 9). This dividend rate is only 90 or 92 per cent. of the scale for temporary residents, and the Treasury will only bring up any deficit which is below the percentage just quoted; there is no intention to make up the full amount of 2s. 6d. for a visit. 2s. for a consultation at the surgery, etc.

This rate of remuneration is too low in these days of increased and increasing expenditure; it ought to be increased by at least 25 per cent.

Will Panel Committees give their representatives instructions to vote for increased panel remuneration at the coming conference? I brought forward a motion last October, but it was lost, owing to some sentiment talked by Dr. Brackenbury about a continued low rate of remuneration being the contribution of the medical profession to the war. I believe that the eyes of some people are at length being opened.—I am, etc.,

JAMES GARDNER,

Honorary Secretary to the Burnley Division, and
Chairman of the Burnley Panel Committee.

Burnley, Sept. 9th.

* * Dr. J. A. Bell of Gloucester, in a letter on the same topic, writes to thank the chairmen, secretaries, and members of Panel Committees and numerous other medical men who have sent him expressions of agreement with the views put forward in his letter published in the JOURNAL of September 1st.

QUO VADIS?

SIR,—Now that with the aid of the officials of the Association the myth of Mr. Lloyd George's 1912 whole-time service scheme—or any other *real* scheme—has been finally exploded, I can pass peacefully to that retirement upon which Dr. Fordyce so kindly congratulates me.¹ An additional comfort will be that the refusal of both Dr. Fordyce and Dr. Davies to accept the evidence of responsible officials constitutes a final and striking proof of Dr. Fordyce's own dictum—namely, the impossibility of the disciplinary control of the medical profession. “Vale.”—I am, etc.,

Hove, Aug. 12th.

C. RAWDON WOOD.

THE DISCOVERER OF THE CAUSE OF SLEEPING SICKNESS.

SIR,—Having been on vacation I have only yesterday seen a letter in the BRITISH MEDICAL JOURNAL of August 11th, in which Sir Ray Lankester tries to minimize the part Castellani had in the elucidation of sleeping sickness. I would ask the reader to keep in mind that the Commission sent to Uganda in February, 1903, by the Royal Society consisted of two members only, Sir David Bruce and myself. We arrived in Uganda together on the same day, by the same boat. I am therefore in a unique position to know the exact history of the investigation. I have given all particulars in previous letters on this subject (see *Journal of Tropical Medicine*, July 15th, 1908, and *Times* of July 23rd, 1908, August 20th, 1908, August 29th, 1913, and September 22nd, 1913), and any one taking the trouble to read them will see how grotesque is Sir Ray Lankester's claim that the major part of the credit for the discovery should be given to Sir David Bruce. How can Sir Ray Lankester make this assertion when even in the history given by Sir David Bruce himself (inserted in the official reports without my knowledge) it is stated that before the Commission started work, Castellani gave information that he had found trypanosomes in the cerebro-spinal fluid of some sleeping sickness patients, and

¹ BRITISH MEDICAL JOURNAL, August 11th, 1917.

that he described and taught the method of detecting the parasite, and showed it?

It is stated also that Castellani's "most interesting discovery" led to the rapid and easy elucidation of the etiology of the malady, and that without a knowledge of it the Commission—in Bruce's words—"might have worked in the dark, and, in truth, they might even have returned to England still ignorant as to the true cause of the disease." There is no doubt that Castellani gave great importance to his observations (see my letter to the *Times*, September 22nd, 1913). My assertions have never been contradicted either by Sir Ray Lankester or by Sir David Bruce.

In conclusion, I should like to repeat here what I have always stated in previous publications—namely, to Castellani goes the credit of having first discovered the trypanosome in the cerebro-spinal fluid of sleeping sickness patients; of having first connected it with the etiology of sleeping sickness, and of having first published it. To myself, equally with Sir David Bruce, the credit is due of having very greatly enlarged the researches on the trypanosome and of having first discovered that the parasite is carried by a tsetse fly, *Glossina palpalis*.—I am, etc.,

DAVID NABARRO,

Member of the Sleeping Sickness Commission
London, W., Aug. 29th. of the Royal Society, 1903.

KENT HOSPITALS COMMITTEE.

SIR,—It may interest members of hospital staffs in other counties to know that at a meeting of the members of the medical staffs of hospitals in Kent, held in Maidstone on August 29th at the invitation of the Kent Local Medical Committee for the purpose of forming a hospitals committee for Kent, the following resolutions, and others, were passed by the meeting:

1. That this meeting of members of the medical staffs of hospitals in Kent and of members of the Kent Local Medical and Panel Committees shall form a committee to be known as the "Kent Hospitals Committee."
2. That the members of the Kent Hospitals Committee consist of two representatives from each general hospital and one representative from each smaller hospital, together with three members of the Kent Local Medical and Panel Committees.
3. That members of the medical staffs of the hospitals in Kent meeting at Maidstone on August 29th, 1917, are of opinion:
 - (a) That members of the Kent Hospitals Committee, when formed, and the medical staffs of the hospitals they represent, should not enter into any agreement with the Government, the Local Government Board, or other public body unless and until such agreement has had the sanction of the Kent Hospitals Committee.
 - (b) That the members of the Kent Hospitals Committee and the medical staffs of hospitals they represent should do all in their power to uphold the rulings of the Kent Hospitals Committee, and to abide by its decisions.
 - (c) That no member of the medical staff of a hospital in Kent should agree to attend discharged disabled soldiers as a charity.
 - (d) That no payments should bind members of the medical staffs of the hospitals to sign any certificates, to keep records, or to abide by any new regulations, unless such forms and regulations have been passed and sanctioned by the Kent Hospitals Committee.
 - (e) That when a representative is unavoidably prevented from attending a meeting, his hospital shall have the right to send another member of its medical staff to take his place.

—I am, etc.,

Maidstone, Sept. 3rd.

FRANK COKE, F.R.C.S.Eng.

The Services.

EXCHANGE.

OFFICER in command of a division of stationary hospital near front (Western) would like exchange with officer in similar position at base or elsewhere.—Address, No. 3100, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.

THE sixth edition of *Diseases of the Skin*, by Sir Malcolm Morris, K.C.V.O., has just been published by Messrs. Cassell in a revised and enlarged form. The book has been thoroughly revised by the author with the assistance of Dr. Ernest Dore. The chapters on syphilis have been expanded with a view to the needs of those who are carrying out the new official scheme for the diagnosis and treatment of venereal diseases.

Obituary.

ARTHUR EDWARD PATTERSON, M.D., C.M.,

SENIOR ASSISTANT MEDICAL OFFICER, CITY OF LONDON MENTAL HOSPITAL.

DR. ARTHUR EDWARD PATTERSON, for twenty-five years senior assistant medical officer to the City of London Mental Hospital, near Dartford, passed away after a short illness on August 26th. He was the son of the late Major D. A. Patterson, and received his early education in Aberdeen, subsequently proceeding to Aberdeen University, where he qualified M.B., C.M. in 1885; he obtained the M.D. in 1896. After a short period of general practice he entered upon what was to become his life-work as assistant medical officer to the Derby Borough Asylum. He was appointed senior assistant medical officer of the City of London Mental Hospital on January 1st, 1892. A conscientious, painstaking officer he proved himself to be, and his cheery manner and true kindness of heart ensured his popularity with the staff and endeared him to his patients, who were devoted to him.

Dr. Patterson was a member of the British Medical and Medico-Psychological Associations, and published several articles in the medical papers, one of which, "An analysis of 1,000 admissions into the City of London Asylum," appeared in the *Journal of Mental Science*. At one time he took a keen interest in Masonry, and was past master of the Adelphi Lodge No. 1670.

The first part of the funeral service took place in the Asylum Chapel. The Visiting Committee was represented by Sir George Wyatt Truscott, Bt. (chairman) and several other members.

R. H. S.

THE death is announced of Dr. JOHN AITKEN, at Elie, in Fifeshire. Dr. Aitken received his medical education in the University of Glasgow, obtained the M.B., C.M. degrees in 1878, and proceeded to the M.D. in 1886. In 1897 he obtained the D.P.H. of the Edinburgh Royal Colleges. Forty years ago he began practice in Buckhaven, where he had a large practice and was greatly respected. For a time he was M.O.H. for the joint boroughs of Buckhill, Methil, Innerleven, Lochgelly, and Ladybank. Several years ago he retired from practice owing to failing health, and went to live at Elie. He is survived by a widow and daughter.

BRIGADE-SURGEON GEORGE EDWIN SEWARD, Bombay Medical Service (retired), died at Ryde, Isle of Wight, on August 15th, aged 90. He was born on November 29th, 1826, educated at Edinburgh University, where he graduated M.D. in 1855, and entered the I.M.S. as assistant surgeon on August 4th, 1855. He became surgeon on August 4th, 1867, and surgeon-major on July 1st, 1873, retiring with a step of honorary rank on October 12th, 1884. During the Mutiny he was on service in the Indian navy; he was residency surgeon at Baroda at the time of the trial of the late Gaikwar for complicity in the attempt to poison the Resident, Colonel Phayne; and as residency surgeon at Zanzibar he saw Dr. Livingstone start on his last journey into the interior of Africa.

BRIGADE-SURGEON-LIEUTENANT-COLONEL HARRY ARCHIBALD DE LANTOUR, V.D., New Zealand Defence Forces, died at Invercargill, New Zealand, on June 22nd, aged 68. He was the son of the late Edward de Lantour, of the Bengal Civil Service, and was educated at King's College, London, and took the M.R.C.S. in 1874. He had served for long in the Colonial Defence Force, and had received the Volunteer Officers' Long Service Decoration. He had acted as examiner in public health and medical jurisprudence to the New Zealand University.

DR. GEORGE STANCULEANU, who had been in America for several months on a mission on behalf of the Rumanian Government, died at Stamford, Conn., on July 16th. He was laryngologist to the King and Queen of Rumania, and was a very successful practitioner before the war. The German invasion compelled him to leave his native country, leaving everything behind him.

Medical News.

ON July 16th the American Red Cross Fund amounted to £23,604,274.

A THREE months' course of lectures and demonstrations in hospital administration will be given at the South-Eastern Hospital of the Metropolitan Asylums Board, on Tuesdays and Fridays at 5 p.m., by Dr. F. M. Turner, beginning on October 2nd.

MR. W. F. HASLAM, in commemoration of thirty-six years' association with Birmingham General Hospital, was presented on September 10th with an illuminated address and his portrait in oils, while Mrs. Haslam was presented with a diamond and pearl pendant. Mr. Haslam is retiring from the post of honorary surgeon to the hospital, which he has held for the past twenty-six years.

AN urgent appeal for aid is made on behalf of the Joint Committee of the British Red Cross Society and the Order of St. John, for "Our Day," which has been fixed for October 18th. The needs of the Red Cross work were never greater, and they are increasing every day. "Our Day" is everybody's opportunity to contribute to the comfort, care, and well being of the empire's wounded and stricken heroes. Miss C. May Beeman, the organizing secretary, will welcome offers of assistance addressed to 10, West Bolton Gardens, London, S.W.5.

WE have received the first number of the *National Food Journal*, which is issued by the Ministry of Food (H.M. Stationery Office, price 2d.) as a means of giving detailed and official information with regard to the actions and policy of the Ministry. The first number is dated September 12th, and publication will be continued twice a month. Lord Rhondda contributes a prefatory note, in which he states briefly the broad lines upon which his policy of food control is based, concluding with a statement that the general position of our essential food supplies is satisfactory, but that there is absolute need for economy in the use of all foodstuffs.

ON September 7th, at the Liverpool City police court, Henry Virtue Siddons was committed to the assizes on the charge of making a false statement under the Defence of the Realm Act, and on other charges. At the preliminary hearings it was alleged that the prisoner had forged and uttered two notifications of tuberculosis, adding the letters M.D. after his signature, although he had no qualifications in medicine or surgery. At the hearing on September 7th counsel said that subsequent inquiries had enabled the prosecution to present a number of charges against Siddons which were not known earlier in the case. Evidence in support of various charges against the prisoner having been given he was committed for trial, reserving his defence. In opposing an application for bail, counsel stated that in 1913 Siddons was indicted at the Old Bailey, where it was proved that he had personated a medical man, and he went to prison for nine months. Whilst in custody on that charge the accused had leapt out of a railway carriage window, endangering his life. Bail was refused.

A CIRCULAR issued by the Local Government Board on decisions by the Central Tribunal states that in a recent case the applicant, being dissatisfied with his classification (B 1) by the Recruiting Medical Board, was re-examined by the Special Medical Board, who passed him fit for general service. From the evidence of private practitioners, the Appeal Tribunal came to the conclusion that the man could not be fit for general service, and as there appeared to be no further steps which could be taken to verify his classification, the Appeal Tribunal felt bound to give the man exemption, which they did, for three months. The military representative contended that the tribunal were bound by the decision of the Special Medical Board, and the tribunal accordingly gave him leave to appeal to the Central Tribunal on this question. The Central Tribunal held that, although the greatest weight should be given to a certificate of the Special Medical Board, a tribunal is not absolutely bound to decide in accordance therewith, but must consider and decide upon any evidence which may be laid before them relating to the health of the man. The Central Tribunal repeated that a tribunal is not entitled to grant exemption on the ground of ill health or infirmity alone unless they are satisfied that it is such that the man is not fit for any form of military service. The form of military service the man is fit to undergo is not a matter for the tribunals but for the military authorities. The Central Tribunal remitted the case to the Appeal Tribunal to be decided in accordance with these principles.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are (1) EDITOR of the *BRITISH MEDICAL JOURNAL*, *Aitology, Westrand London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

QUERIES.

W. M. J. asks for suggestions in the treatment of a bad case of nail-biting, in a child 4 years old, in which the ordinary methods have failed. Beyond being rather nervous and excitable the girl is in all other respects well.

LETTERS, NOTES, ETC.

CENTRAL KITCHENS.

MR. CHARLES E. HECHT writes: The executive committee of the National Food Reform Association (14, Great Smith Street, S.W.1) in April last passed a resolution "welcoming the action of the Ministry of Food in recommending communal kitchens as making for individual and national economy and a better nourished population," and received a cordial acknowledgement. Since then the system has been widely adopted, and the saving, both in foodstuffs and in fuel—recently noted with approval by Lord Rhondda—to say nothing of labour, or the opportunity afforded for improving cookery and diminishing waste, is generally recognized. The committee desires to be of service to local authorities and others. It has already been able to assist both public and private promoters of such kitchens.

"A TOO-PUNGENT MOUTH-WASH."

M.D. writes: You have now published two letters from dental surgeons condemning the use for oral purposes of pungent washes, powders, and pastes. A dental surgeon to whom I often send my patients appears almost invariably to advise the use of euthymol tooth paste in cases of pyorrhoea, not only for cleansing the teeth but equally for massaging the gums, after he has himself treated the teeth. The results appear to me to be most satisfactory. I cannot help thinking that the assertion that tooth pastes may cause a marginal gingivitis or interstitial caries is too sweeping.

MEDICAL APPOINTMENTS IN EGYPT.

WITH regard to the paragraphs on medical practice abroad in the Educational Number of the *JOURNAL*, the Director-General of the Egyptian Public Health Department sends us the following note concerning certain medical appointments which occur from time to time in Egypt:

The medical appointments made in the Department of Public Health belong to two main categories:

(a) Temporary Inspectors: Appointment on two years' contract at £600 per annum (with certain allowances, rising to £720 per annum).

(b) Divisional Inspectors: Appointment at £480 per annum (with certain allowances), rising to £600 per annum, with appointment on the pension list after two years' probation if the candidate proves satisfactory.

Candidates for both categories of appointments should be not more than 30 years of age, and should be unmarried.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

THE MENINGOCOCCUS OF WEICHELBAUM.

BY

EDWARD C. HORT, F.R.C.P. EDIN.,

DIRECTOR OF THE CONSTANCE TROTTER RESEARCHES; HONORARY
PHYSICIAN TO THE ADDINGTON PARK WAR HOSPITAL; AND
DIRECTOR OF THE BACTERIOLOGICAL LABORATORY,
ADDINGTON PARK.

The Teaching of Recent Experimental Research.

NOTWITHSTANDING the results of recent experimental research, it is still taught, and it is in consequence widely believed, that the meningococcus of Weichselbaum is itself the direct causal agent of that form of epidemic cerebro-spinal fever which is sometimes spoken of as meningococcal meningitis.

It is also still taught, and the teaching is accepted without question, that the meningococcus, as one of the "lower" bacteria, is an organism with an extremely simple life-cycle, which begins and ends with binary fission into two equal parts. A meningococcus—so runs the legend—always arises directly from a meningococcus, and in no other way.

As regards the first of these propositions—that the meningococcus is itself the direct cause of the disease which bears its name—I showed by experiment in 1915, and this, in conjunction with Captain A. H. Caulfield, I amply confirmed in the following year:

1. That cultures of the meningococcus in cerebro-spinal fluid or in suitable laboratory media frequently contain a minute filterable virus, which is just as pathogenic to monkeys (though not necessarily productive of meningitis) as are unfiltered cultures.

2. That the meningococcus itself appears to be inert, in so far as the production of systemic infection is concerned, whether the cultures be of the so-called epidemic strains, or of admittedly harmless types of carrier strains.

As a result of these experiments, it became clear that the pathogenic results obtained in the past by injection into animals of living cultures of the meningococcus, believed at the time of injection to be pure cultures, are in reality to be ascribed to the injection of impure cultures, the "impurity" consisting in the minute filterable virus described.

It became manifest, in short, as a result of these experiments, that there is no reliable evidence that the meningococcus as such is itself responsible for the disease, mere constancy of presence of the organism, even when combined with agglutinability, being of little value as proof of direct etiological relationship.

Demonstration of the presence of this filterable virus in meningococcal cultures had, moreover, this important result, that it threw grave doubt on the validity of the second proposition to which I have referred, namely, that the reputed causal organism of the disease is a bacterium with a simple life-cycle, which begins and ends with equal binary fission. It unmistakably suggested, in fact, that the meningococcus represents one phase only—the filterable virus representing a second phase—in the life-cycle of an organism which has not yet been described, though, owing to the fact that the experimental method of investigation was mainly employed, it was not then possible to prove by ocular demonstration that this is indeed the case.

Studies in the Morphology of Meningococcal Cultures.

To-day, however, as a result of direct morphological studies of cultures of the meningococcus—studies which are capable of ready verification by the adoption of an extremely simple technique—I am able to confirm and amplify the results obtained already by the experimental method. I am, in short, now able to produce direct morphological evidence that the meningococcus is not a bacterium at all, and that both it and the filterable virus referred to do actually represent different phases in the life-cycle of an ascomycotic organism which has hitherto been believed to be an involution form of the meningococcus. Before, however, presenting the evidence on which these statements are based, I wish to make it perfectly clear that even now the complete life-cycle, in the human host, of the causal organism (of which the meningococcus only represents a saprophytic phase) of cerebro-spinal fever has not been worked out, and that much work on this subject still remains to be done.

This communication deals mainly with the morphological characters of the meningococcus and of its so-called giant forms. It is necessary, therefore, briefly to summarize what is at present known of their chief morphological characteristics.

The Present State of Knowledge of the Morphology of the Meningococcus.

The normal meningococcus of Weichselbaum, say the textbooks, is a Gram-negative coccus, with an average diameter of about 1μ , which may be seen either alone, or in pairs, the latter often showing flattening of the opposed surfaces. When occurring as single cocci it is generally assumed that each living organism will presently undergo equal binary fission, and in the case of many single individuals this, of course, often happens. The meningococcus appears also to be sometimes grouped in triad formation, and sometimes in tetrads. It is said never to appear in chain formation, except as the result of accidental apposition.

In addition to the normal meningococcus, a few of the textbooks—notably that of Heiman and Feldstein—describe the so-called giant forms. These are said to attain to from four to five times the size of the normal coccus, and notwithstanding the fact that they are believed to disappear from solid subcultures in from twenty-four to forty-eight hours, they are usually looked upon as involution forms, or swollen decadent meningococci. These giant forms stain, say Heiman and Feldstein, deeply with the counter-stain employed in Gram's method, as do also some of the single normal-sized "meningococci," in contrast to others of the single normal cocci, as well as the diplococcal forms, both of which take the counter-stain but lightly.

In addition to the normal-sized meningococci, with an average diameter of about 1μ , it has long been recognized that sometimes considerably smaller forms may be seen, with an average diameter of about 0.5μ , and intermediate forms, above the normal organism in size, but below the giant forms, have also been described.

This, then, completes the textbook accounts of the morphology of the meningococcus. It is, however, almost exclusively based on observations of stained fixed films from cultures on solid media, practically no observations having been recorded of the morphology of the organism in stained fixed films from liquid cultures, and none at all of its morphology in wet stained or unstained preparations. And, lastly, no extensive observations appear to have been undertaken of the development of the organism on the warm stage, whether in liquid or on solid media.

In other words, apart from the usual perfunctory examination of the organism in fresh cerebro-spinal fluid, its claim to be considered as a bacterium at all finds its sole justification in the results obtained by the examination of stained dead individuals direct from cultures on solid media.

Now, all deductions as to the botanical position of micro-organisms drawn from the study of stained fixed films are notoriously dangerous unless controlled by direct examination of the living unstained organism, and by observation of development on the warm stage from a single individual. If we add to this statement the reflection that, however convenient artificial solid media may be for the identification of species (by the subsequent application of cultural, fermentative, and serological tests), artificial solid media do not occur in nature, it is not surprising that the application of more scientific methods of study should reveal the fact that the meningococcus is not what it appears.

The Morphological Characteristics of the Meningococcus as Studied in Liquid Cultures.

As I have stated, it is essential, in order satisfactorily to study the morphology of the meningococcus and to determine its real nature, to employ liquid cultures, and to examine therein—

1. Unstained and stained living organisms at room temperature.
2. Development of single individuals on the warm stage.

This should be supplemented, and not replaced, by examination of stained and of unstained fixed films, using for the latter Benians's Congo-red method, or other suitable adsorption method.

Examination of Unstained Living Organisms at Room Temperature.

The method of observation I have found to give the most satisfactory results, allowing of photography with the Pointolite nitrogen lamp, is to make a liquid cell containing a liquid culture under firm pressure between a glass slide and a cover-slip, sealed, to prevent drying and escape, with paraffin. This allows the liquid medium employed to remain liquid at room temperature for at least forty-eight hours. Slide and cover-slip are soaked for twenty-four hours in fuming nitric acid, and are then placed in absolute alcohol till ready for use, when they are finally flamed. The culture is centrifuged before filling the cell in order to enable the observer rapidly to find the various types of organism present in pure cultures of the meningococcus in serum broth or other suitable liquid medium, such as Naegeli's medium containing 2 per cent. glucose and a trace of albumin.

Prolonged examination of, for example, Gordon's strain No. 4 in serum broth, controlled by examination of the same strain (the same sample) in Naegeli's medium, revealed the following types in a liquid cell prepared as above described:

1. Meningococci in diplococcal form of normal size.
2. Giant meningococci in large numbers.
3. Triad groups.
4. Tetrad groups.
5. Short streptococcal groups, the members of the chain being usually unequal in size.
6. Very minute organisms, many being approximately 0.1 to 0.2 μ in diameter, or even less.
7. Intermediate single cocci of every conceivable size between about 0.1 μ and about 4 to 5 μ .
8. One or two bacillary and filamentous forms.

More detailed description of these types is for the moment deferred.

Examination of Stained Fixed Films.

Examination of several hundred Gram-stained films from 46 consecutive acute cases of cerebro-spinal fever in which the meningococcus was isolated and identified, and cultivated in serum broth, gave in every case the same essential results as those detailed in the last paragraph (1 to 8). In all the cases the normal-sized meningococci took up the counter-stain, neutral red or carbol-fuchsin, relatively lightly. In all the cases the giant forms, the triads, the tetrads, and large numbers of the single undivided cocci from about 0.2 μ upwards all took the counter-stain deeply. The occasional bacillary and filamentous forms seen in the majority of the cultures did not as a rule take the counter-stain deeply.

In all cases the outline of the giant forms when stained by Gram's method was relatively blurred as compared with their distinct appearance as living unstained organisms. This also applied to all films stained with Leishman's stain, Jenner's stain, carbol-thionin, methylene blue, Löffler's stain, eosin, carbol-fuchsin, neutral red, or safranin. Previous treatment of the films with iodine tetrachloride vapour, or with saturated solutions of iodine in potassium iodide solution, also failed to render distinct the outline of the giant forms when subsequently stained. Staining of all the kinds tried, in fact, appeared to give an entirely fallacious idea of the true form and structure of these giant forms.

Examination of Unstained Fixed Films: Congo-Red Method.*

This method requires some months' practice in order to obtain familiarity with its fallacies. Once mastered, however, it gives invaluable results, provided always that—as here—these results are controlled by careful examination of unstained living organisms, both at room temperature and on the warm stage. The results obtained are summarized in the accompanying chart of selected giant meningococci from a large number of fields, and are self-explanatory. Endosporeulation and gemination, particularly the latter, are well seen. A large number of excellent photographs of giant meningococci undergoing well-marked endosporeulation have been taken for me by Mr. Martin Duncan, as well as numerous autochromes. Owing to exigencies of space and paper these photographs cannot be reproduced here.

Examination of Living Organisms at Room Temperature and on the Warm Stage.

It is now necessary to describe in fuller detail what may be observed by examination at room temperature of unstained living organisms from liquid cultures of the meningococcus, as well as what may be learnt by observation of development on the warm stage.

To avoid repetition, these may be taken together.

In examining pure cultures of the meningococcus in liquid media by the method of direct observation of unstained living organisms under pressure, the most striking feature—once the attention has been called thereto—is the presence of spheroidal bodies of all sizes up to about 5 μ , with a different refractive index to that possessed by genuine meningococci. To the trained observer this difference in refractive index is alone sufficient to enable a distinction to be drawn between genuine and spurious meningococci, and this applies to the smallest organisms present as well as to the largest. Many of these spheroidal bodies, on careful watching, are seen, in favourable circumstances, obviously to be undergoing unequal binary fission or gemination. Others, again, are clearly undergoing endosporeulation, with or without accompanying gemination. Multiple endosporeulation is in many cases readily to be made out, as also is rapid Brownian movement of what appear to be metachromatic granules, which as a rule can easily be distinguished from the true endospores. Most of the young spheroidal bodies when undergoing gemination, or endosporeulation, or both, have a clearly defined peripheral rim, which serves readily to distinguish them from genuine meningococci (with the ill-defined periphery characteristic of their appearance) when viewed with a good oil-immersion fluorite lens under optimum conditions of illumination. That these spheroidal bodies are genuine asci there can be little doubt, the larger forms being identical with the giant meningococci, as they have hitherto been called.

That the giant meningococcus is not a bacterium is, of course, proved by the facts of gemination and of endosporeulation, the former of which appears to be, from warm stage observation, the main method of its reproduction in young cultures. It is, however, not the exclusive method, as some of the asci divide, radiating from a central space, into three equal segments, and others into four equal segments, the segmentation being holocytous instead of merocytous,* as in the case of the endospore production. This holocytous segmentation of asci into groups of triads and tetrads, and possibly into pairs, though the latter I cannot yet vouch for, is reminiscent of the equal fission observed in the schizogonic saccharomycetes. In the case of meningococcal cultures, however, it appears to be combined in one species with gemination and endosporeulation. The new individuals formed by triad and tetrad formation may be either spheroidal or pyramidal in shape, the latter form apparently being only temporary, and later appearing to assume a spheroidal form.

In the above description I have said that there are minute forms of the "giant meningococcus" as well as large forms, and that this is undoubtedly the case is shown by the fact that even very minute forms may be seen to be undergoing gemination, or endosporeulation, or both, apart from the evidence afforded by differences in refractive index and peripheral outline, as compared with genuine meningococci. We are therefore now in a position to explain the true nature of the numerous single cocci which may be seen in any liquid meningococcal culture. Many of these are undoubtedly meningococci about to undergo equal binary fission; others, on the contrary, will never undergo equal binary fission, but are, in point of fact, young asci, which are capable of undergoing, and often do undergo, gemination and endosporeulation before attaining to their full size. Others, again, while still minute, will split into groups of threes or fours without presenting any evidence of accompanying gemination or endosporeulation. Some asci undergo secondary gemination in rapid succession, the daughter and granddaughter cells still remaining attached, each to its mother cell, and in this way a streptococcal grouping is sometimes formed which is not the result of accidental apposition.

As in the case of recognized ascomycetes, the "giant

* Holocytous signifies cleavage through the entire depth of the cell, as opposed to merocytous, cleavage through a portion of the cell, as in sporulation.

Camera lucida drawing of "giant meningococci." Photograph $\times 1,500$.

meningococci," whether large or small, are all potential asci, with the possible exception of those which undergo schizogonic segmentation, and as such all these spurious meningococci, with the exception stated, are potentially capable of undergoing in their turn gemmation and endosporulation. From prolonged warm-stage observation, there is little doubt that genuine meningococci arise by multiple endosporulation from spurious meningococci, or asci, but there is as yet no evidence that the true meningococcus develops again directly into an ascus, as, on the contrary, undoubtedly do the ascus buds. For a time, at least, on solid laboratory media, equal binary fission of the meningococcus becomes stable and fixed, though I have been able to obtain evidence, at present incomplete, that some meningococci (endospores), either before or shortly after escape from the ascus, will show mycelial sprouting in suitable liquid media and so complete the cycle. Considering, however, the tendency to suppression of the mycelial phase in many of the ascomycetes, it is perhaps not to be wondered at that the mycelial aspect is much more difficult to study in laboratory cultures of the meningococcus than is the ascus aspect.

It has been stated above that in serum-broth cultures—and this also applies to cultures of the meningococcus in Naegeli's synthetic medium—very minute organisms can frequently be made out, which I have elsewhere shown to be capable of passing through Chamberland filters. These minute organisms, close to the vanishing point of vision, may, under favourable conditions, be seen in well-developed asci (giant meningococci) and in some cases may be watched in the process of extrusion therefrom. I have not been able to satisfy myself that these will subsequently develop into meningococci, though they do undoubtedly in some cases develop into unmistakable organisms, as seen with monochromatic light, of a globoid nature. Exactly similar bodies, Gram-negative and globoid in form, are often to be seen in incubated meningococcal filtrates (Chamberland F.), though their relationship to genuine meningococci is still a matter of uncertainty. They appear, however, to form a connecting link between invisible filterable virus and Weichselbaum's organism.

It is now necessary very briefly to deal with certain criticisms which might, perhaps not unreasonably, suggest themselves to students who are not familiar with the appearances of meningococci in liquid media when examined in the living state. Both forms of reproduction—gemmation and endosporulation—I have repeatedly watched on the warm stage. Any suggestion therefore that the asci and ascospores are of the nature of artefacts, as from a study of dried preparations alone a casual observer might be pardoned for suggesting, can be summarily dismissed. This applies also to the suggestion that the appearance of gemmation under isotonic conditions has been simulated by plasmolytic changes such as may be observed in red and white blood cells under anisotonic conditions. The further suggestion that the "giant meningococci" (asci) represent involution forms is practically disproved by the facts that they can be sometimes seen in small numbers in cerebro-spinal fluid collected within a few hours of the onset of the disease; that they may be seen in small numbers in 12-hour old primary colonies on solid media if they be diligently searched for, and that they may grow and bud freely in enormous numbers in young liquid cultures, such as serum broth and in subcultures therefrom. And finally, as already stated, quite small young budding forms can be frequently seen undergoing endosporulation, especially after subcultivation from liquid cultures to serum-agar slopes. The term "involution form," in fact, is one that has in the past been much too freely applied to organisms the true nature of which escapes us, and under the optimum cultural conditions obtaining throughout its application here would be worse than unreasonable.

The same criticism applies to the facile suggestion that the organisms here described are contaminants. In connexion with the question of contamination, it is well to remember that it is just as dangerous—provided a good technique has been employed—to assume that a given organism is a contaminant as to assume that it is not. As the appended detailed account of the technique here employed will show, every device known to modern bacteriological science has been employed to prevent contamination. Any doubt remaining as to the adequacy of these devices should be dispelled by the fact that

these organisms were found and cultivated in 46 consecutive cases of the disease, an achievement which, if the organism were a contaminant not deliberately introduced, it would pass the wit of man to reproduce. And, finally, the observations here recorded have only to be repeated for the impartial student to be convinced of their accuracy. In every one of these 46 cases the meningococcus has been isolated and fully identified by its staining reactions, its morphology, its sugar reactions, and its serological reactions, as well as by well-defined cultural reactions. I have not in primary serum-broth cultures found asci in any case apart from the meningococcus, and in no case has the meningococcus been found without asci being also found. I have never been able to cultivate them in serum-broth culture apart from the meningococcus, and in every apparently pure primary culture of the meningococcus the organism has always been found if diligently searched for, and in none of the control culture tubes has any growth been found. The best and most certain method of demonstrating the presence of asci has been, in my hands, by subculture from single colonies of meningococci on serum-agar, itself inoculated with incubated cerebro-spinal fluid. This subculture, however, must be into liquid media, an excellent medium being equal parts of tested horse serum and broth, and there is little doubt but that the real nature of the "giant meningococcus" would have been noted and recorded long ago if the routine use of solid media had not been generally required for purposes of identification of the normal meningococcus.

Details of Technique Employed.

The technique I have mainly employed for detection and cultivation of the asci described is as follows:

1. Cerebro-spinal fluid from a suspected case of the disease is discharged direct into a sterile glass flask with a specially ground glass stopper provided with a sterile rubber cap sufficiently large to come well down over the neck of the flask. In all but six of the cases only samples of fluid withdrawn at first lumbar punctures have been employed.
2. On arrival at the laboratory the centrifuged deposit from a small quantity of the fluid is examined.
3. The remainder of the fluid is then incubated at 37° C. for a period varying from twenty-four to forty-eight hours.
4. A further volume of the fluid is now withdrawn from the flask and is centrifuged and examined.
5. Serum-agar slopes—and sometimes in addition serum-agar plates—are now inoculated, the plates in series, with considerable volumes of the incubated cerebro-spinal fluid.
6. On the following day likely single colonies are picked off and are individually spread on to fresh serum-agar slopes to provide a free confluent growth.
7. On the following day the entire growth of each slope is inoculated into serum-broth tubes, which are incubated for forty-eight hours.
8. From the serum-broth tubes fresh serum-agar and agar slopes are inoculated for serological tests, and lactose, saccharose, glucose, mannite, and dulcitate tubes are also inoculated from the same source.
9. Samples of the serum-broth tubes are at the same time, and subsequently every day, centrifuged and the deposits examined.
10. The filtered serum employed in each case is thoroughly tested, as regards sterility, by complete bacteriological and experimental tests, monkeys being employed for the latter. By taking these precautions and by replating at each stage and retesting from single colonies, both with fermentation and serological tests, as absolute a guarantee as it is possible to obtain by observation of cultures from single colonies is assured.

However useful for purposes of identification and for ensuring the absence of contaminants, cultivation from single colonies nevertheless cannot give an absolute guarantee of purity of culture. To obtain this only two methods are open to us. The first is to pick off single meningococci from a solid culture and to place individual organisms into a separate tube containing a suitable liquid medium in the hope of successful cultivation therefrom.

This, of course, is the classical method, and in theory it is ideal. In practice, however, it cannot be relied on, and for this reason: As I have previously shown, the presence

of the minute filterable virus frequently to be found in meningococcal cultures makes it impossible to be certain that in picking up a normal sized meningococcus one is not at the same time picking up some of this filterable virus. And this objection also applies to the presence of the very minute organisms described above. Now the smallest of these forms—and this is a point I have repeatedly tested—are quite invisible as organisms under a dry lens and the highest compensating ocular that will allow of good illumination. Even with a magnification of 3,000 obtained with a 1.5 mm. apochromatic oil-immersion lens and the appropriate tube length and compensating ocular it is still impossible to be certain that one organism, and one only, has been picked up. The photograph of the camera lucida drawings will illustrate the point of this objection, which applies both to Barber's method and to the fragmented cover-slip method. The only alternative, therefore, is actually to watch on the warm stage growth from a single organism, and even here—on account of these extremely minute forms—the problem is one of great difficulty, which is accentuated by the fact that growth and gemmation of asci is unsatisfactory on solid media, necessary as solid media may be for observing endosporulation. It became necessary, therefore, to use methods of observation of individual organisms in liquid cultures other than the hanging drop method, which is, of course, useless for fine work owing to the curve and depth of drops.

The method I have adopted involves, as stated, the use of shallow cells covered with sterile slips, and the method ensures relative immobilization of the organisms under observation. On the whole it gives satisfactory results.

These results, however, require the greatest care in interpretation, owing to the presence, first, of the filterable virus and of the almost invisible organisms referred to, early gemmation and even endosporulation being often exactly simulated by minute organisms brought into apposition by slight streaming movements still persisting; and owing, secondly, to slow rotatory and dipping movements. These movements lead to error, unless careful and prolonged watch is made, because an early bud, or a minute endospore, under observation may either temporarily vanish from view, or without having been previously seen may come into view for the first time, and simulate either a fresh bud or an endospore.

In all cases, therefore, most tedious and prolonged observation is necessary, which has to be repeated again and again with fresh cultures, as disappointment is frequent owing to death or arrest of growth of an individual organism under observation.

ILLUSTRATIVE FERMENTATION AND SEROLOGICAL TESTS OF THE SERUM-BROTH CULTURES EMPLOYED IN THE ABOVE OBSERVATIONS.

Fermentation Reactions.

In the case of all the fourteen cultures, details of which are here recorded, no reaction was observed in lactose, saccharose, mannite, or dulcitol.

In twelve of the cultures acid was produced quite definitely in glucose, in the remaining two cultures no acid being produced in glucose.

In every case incubation at 37° C. was continued for eight days.

Serum Reactions.

Dilutions:	1:4.	1:8.	1:16.	1:32.	1:64.	1:128.	1:256.	Control.
Culture 1 ...	C	C	C	C	C	C	C	Nil.
Culture 2 ...	C	C	C	C	C	P	Nil	Nil.
Culture 3 ...	C	C	C	C	P	Nil	Nil	Nil.
Culture 4 ...	C	C	C	C	C	Nil	Nil	Nil.

C = Complete agglutination. P = Partial agglutination.

In the case of these four cultures the dilutions were made from undiluted meningococcal serum supplied by the Lister Institute: Titre 1 in 250; No. cl; date of tubing, February 9th, 1916; dates of agglutination, March 8th, 1916; March 4th, 1916; April 29th, 1916; April 29th, 1916.

Incubation at 37° C. was allowed for twenty-four hours before reading, plus one hour at room temperature.

The agglutination tests of the remaining ten cultures were kindly carried out by Dr. Lawes, using Gordon's method for identification of "strains."

The agglutination tubes and their contents were incubated at 56° C. for twenty-four hours before being read.

Serum Reactions.

	Normal.	I.			II.			III.			IV.

Culture 14 ...	-	-	-	-	++	++	++	-	-	-	-	-	-

Cultures 8 and 9, 11 and 12, 13 and 14, were from three cases.

Cultures 1 to 7, as well as culture 10, being from eight separate cases. A, B, C represent respectively dilutions 1 in 100, 1 in 200, 1 in 400.

Conclusions.

1. The so-called giant meningococcus is not a bacterium. It represents an ascual stage in the life-cycle of an organism allied to the ascomycetes.*

The ascus may be either large or small, or of any intermediate size (0.2 μ to 5 μ).

2. The meningococcus of Weichselbaum is not a bacterium. It is an ascospore, derived from the "giant meningococcus" by a process of endosporulation.

3. The filterable meningococcal virus of my earlier papers probably represents a stage in the life-cycle of the ascomycetic organism described.

4. The true nature of the meningococcus and its alleged giant forms has hitherto been missed because of the practically exclusive use of solid media for purposes of identification, and because direct examination of unstained living organisms, including warm-stage development in liquid cultures, has not been carried out.

An Experimental Investigation

OF

THE SUITABILITY OF THE MORE SOLUBLE SALTS OF QUININE AND CINCHONINE FOR INTRAVENOUS INJECTION.

BY

SIR LEONARD ROGERS, Kt., C.I.E., M.D., F.R.C.P., F.R.S.,

PROFESSOR OF PATHOLOGY, CALCUTTA.

THE most soluble salt of quinine—namely, the bi-hydrochloride—has for many years been given intravenously in malaria, although only, as a rule, in very severe infections with cerebral symptoms. The method has gained a reputation for being dangerous, although I have long thought this to be due to the extreme class of cases in which it is generally used rather than to the method itself. Nevertheless, the intravenous route is apparently the most efficacious, as shown by the fact that some cerebral cases of malaria can be saved by it when quinine by the mouth or even subcutaneously would be too slow in its action to be trustworthy. The following experience helped to convince me of this fact. In a case with high continued fever, leading to a suspicion of typhoid, I found very numerous malignant tertian parasites in every field of the microscope, and, recognizing a very dangerous infection, 10 grains of bi-hydrochloride of quinine was at once given intravenously, with the result that the temperature fell finally to normal the next morning.† Some years later I found equally dangerous malignant tertian infections on

* The mycelial or "bacillary" phase is still the subject of study, and will be dealt with separately. Owing to the variable number of ascospores (meningospores) which the ascus (meningococcus) contains, and owing to the absence of perithecia, the organism here described is provisionally placed amongst the hemiascomycetes, instead of amongst the ascomycetes proper.

† See Chart 50, page 227 of my *Fever in the Tropics*.

examining blood slides of two fever cases in another hospital, and advised quinine intravenously. The medical man in charge, however, considered this method to be too dangerous, and gave large doses of quinine up to 50 grains a day by the mouth. One patient became comatose on the following day, and the other no less than three days later, and both died of cerebral malaria, in striking contrast with the above successful case.

At the present time there is urgent need, especially in connexion with military operations in malarial areas, for improvement in the treatment of malaria in the direction of trying to obtain complete elimination of the parasites with consequent prevention of recurrences of the disease, apart from new infections. In January last¹ I recorded having observed the disappearance of crescents from the blood in three consecutive cases following intravenous injections of tartar emetic, but pointed out that the drug had much less effect on the intracorporeal stages of the parasites, and suggested its use during convalescence after the fever had been checked by quinine, in the hope of lessening subsequent relapses. Owing to the malarial season having barely commenced, I have not had any further opportunities of trying this method, but I have heard from two of the three first patients that they had remained free from malarial relapses for some time. On the other hand, Low and Newham² have recorded a failure in a single case, and Brodribb³ a success. The only report of an adequate test which I have yet seen is that of Captain A. J. Orenstein and Lieut.-Colonel W. Watkins-Pitchford, Director of the South African Institute for Medical Research,⁴ to whose courtesy I am indebted for a reprint of their paper. They record a series of 24 crescent cases among soldiers from German South-West Africa treated by quinine, followed by tartar emetic intravenously in accordance with my suggestion. In 10 of them the crescents disappeared after one injection of 0.04 gram, in 6 after two injections of 0.04 and 0.08 gram, and in the remaining 8 after one or two additional doses of 0.12 gram, no single failure having been met with. Quinine had previously been given for from twelve to forty-nine days without any effect on the crescents. Two cases examined one month and sixty-four days later respectively were still free from crescents. No cases had returned with a relapse at the time of their report. These results justify further trials of my method, while it would be of great interest to treat alternate cases during convalescence with tartar emetic, keeping the rest as controls. In benign tertian affections they obtained no such effects.⁵

At the suggestion of Sir Ronald Ross I have turned my attention to the investigation of methods of administering quinine, and, in view of the experience mentioned in the opening paragraph of this paper, I selected the intravenous route with a view to ascertaining in what form and strength the drug can be safely and conveniently administered in sufficient doses to afford hope of completely curing recently acquired infections so that relapses can be prevented. In the present paper I propose to record as briefly as possible the results I have obtained regarding the effects on the blood and the toxicity of the more soluble salts of quinine, and of two such salts of cinchonine in different dilutions when given intravenously in animals, and to mention trials of two of them on fever patients.

The Effects of the More Soluble Salts of Quinine and Cinchonine on Human Blood Serum.

The first point to be determined was the compatibility of different dilutions of the salts with human blood. MacGillchrist,⁶ who has done much work on the cinchonal alkaloids, has expressed the opinion that quinine salts are unsuitable for intravenous injection except in the extreme dilution of a single dose in several hundred cubic centimetres of saline, because he found that even in considerable dilution they caused gelatination or precipitation of blood serum on standing. As, however, solutions when injected intravenously do not stand in the blood, but are very greatly diluted within a few seconds, the immediate effect of given dilutions of the alkaloids on serum appears to be what we want to know. With the help of my friend Captain A. J. Shorten, I.M.S., I have tested this point, and

¹ Since writing the above I have heard from Sir Ronald Ross that no effect had been obtained with tartar emetic on any stage of the malarial parasites in a large number of relapsing cases in England, mainly of the benign tertian variety; so, in spite of the favourable South African results, it is now clear that tartar emetic will not solve the problem of malarial relapses.

have embodied the main data obtained in Table I, which gives the solubilities, quinine content, and the immediate and remote effects of adding the different dilutions noted to an equal quantity of human blood serum.

TABLE I.—*Immediate and Remote Effects of Quinine and Cinchonine Salts on Human Blood Serum.*

Salt.	Solubility.	Quinine Content.	Dilution.	Immediate Effect.	Remote Effect.
Quinine bi-hydrochloride	1-1	81.6 %	1-2 1-10 1-100	Nil Nil Nil	Gelatinous. Ditto. Nil.
Quinine urea	1-1	59.2 %	1-2 1-5 1-10 1-100	Nil Nil Nil Nil	Gelatinous. Slightly turbid only. Ditto. Nil.
Quinine hydrochlor sulphate	1-2	74.3 %	1-2 1-10 1-100	Nil Nil Nil	Gelatinous and precipitated. Ditto. —
Quinine lactate	1-10	78.3 %	1-20 1-100	Thick precipitate Nil	Thick precipitate. Turbidity.
Quinine acid hydrobromide	1-7	60.0 %	1-10 1-20 1-100	Slight precipitate Slightly turbid Nil	Thick precipitate. Marked turbidity. Nil.
Quinine bisulphate	1-11	59.1 %	1-10 1-20 1-100	Slight precipitate Slight turbidity Nil	Thick precipitate. Marked turbidity. Nil.
Hydroquinine hydrochloride	—	—	1-10 1-20 1-100	Thick precipitate Ditto Turbid	Thick precipitate. Ditto. Some precipitate.
Quinine periodide	1-20	48.4 %	1-20 1-100	Thick precipitate Slightly turbid	Thick precipitate. Precipitate.
Cinchonine bi-hydrochloride	1-1	—	1-3 1-10 1-100	Nil Nil Nil	Gelatinous and precipitated. Slightly turbid. Ditto.
Cinchonine acid hydrobromide	1-5	—	1-10 1-100	Nil Nil	Gelatinous and precipitated. Slightly turbid.

The data in Table I allow the more soluble salts of quinine and cinchonine to be divided into three classes. The first have no immediate effect on blood serum even in the strongest solutions, and include the bi-hydrochloride, urea, and hydrochlor sulphate of quinine and the bi-hydrochloride and acid hydrobromide of cinchonine, all of which are highly soluble. The second class produce an immediate turbidity of very slight degree of precipitation in concentrated solutions of 1 in 10, but no immediate or remote change in dilutions of 1 in 100, and include quinine acid hydrobromide and quinine bisulphate. The third class cause an immediate dense precipitate in blood serum in dilutions of 1 in 10 and 1 in 20, and include quinine lactate, quinine periodide, and hydroquinine hydrochloride, the last also producing an immediate turbidity in a dilution of 1 in 100.

As far as the effects on the blood serum are concerned, these data appear to indicate that the three quinine and two cinchonine salts in the first class would be quite safe for intravenous use in dilutions of 1 in 10, or even less, while the two in the next class would probably be safe, in view of their slight immediate effect on the serum in 1 in 10 solutions and their rapid dilution in the blood stream to below 1 in 100, which dilution has no great effect on the serum. The last three would not appear to be suitable for use intravenously as they produce an immediate dense precipitate in blood serum, although hydroquinine hydrochloride has been recommended for this purpose.

Effect of the More Soluble Salts of Quinine and Cinchonine on the Coagulability of the Blood.

This has been tested in order to exclude any possibility of intravascular clotting being produced by the injections. Equal quantities of solutions of different strengths in

normal saline were mixed with equal quantities of fresh finger blood in Wright's tubes and the coagulability times noted. The results showed such a uniform diminution of the coagulability time in the strong solutions and in 1 in 100 dilutions, as compared with controls in which normal saline took the place of the alkaloid solution, that it is unnecessary to give details of the experiments, which appear to exclude any danger of intravascular clotting following intravenous injection of these salts. Moreover, no immediate naked eye change was produced in the colour of the haemoglobin by any of them.

The above preliminary experiments on the action of the more soluble salts of quinine and cinchonine on blood, therefore, indicate that, with the exception of quinine lactate and periodide and hydroquinine hydrochloride salts, all those tested are likely to be safe for intravenous injection in concentrations of at least 1 in 10, which would allow of 1 gram being given in 10 c.cm. and so make the intravenous method quite convenient clinically.

The Toxic Action of the More Soluble Salts of Quinine and Cinchonine on Paramoecia.

A series of experiments has also been carried out with the more promising quinine and cinchonine salts with water paramoecia on similar lines to those I used in testing the alkaloids of ipecacuanha.⁶ MacGilchrist⁶ has recorded experiments on the action of cinchona alkaloids on paramoecia as observed under the microscope. I have found it more convenient, and I believe more accurate, to make the dilutions in small test-tubes and note the strengths which kill all the paramoecia in different times as observed with a hand lens, because some are killed much sooner than others, and as only a few can be watched under a microscope in a small drop of fluid, an accurate end point is difficult to obtain by that method. Table II gives the average figures obtained by four consecutive experiments with dilutions of 1 in 20,000, 1 in 30,000, etc., up to 1 in 70,000. Each set of experiments, including all the seven salts in the table, was completed at one time, so that the culture was exactly the same for each series. The dilutions were made in such a manner that the mixture contained the alkaloid in the strengths mentioned, and the results were noted up to eighteen hours.

TABLE II.—*The Relative Lethal Action of Quinine and Cinchonine Salts on the Protozoal Water Paramoecia.*

Salt.	Average Lethal Strength against Paramoecia.	Quinine Content.	Relative Toxicity against Paramoecia.
Quinine bi-hydrochloride ...	1 in 50,000	81.6%	614
Quinine urea	1 in 30,000	59.2%	507
Quinine hydrochlor sulphate	1 in 40,000	74.3%	537
Quinine acid hydrobromide	1 in 40,000	60.0%	666
Quinine bisulphate	1 in 30,000	59.1%	550
Cinchonine bi-hydrochloride	1 in 30,000	—	—
Cinchonine acid hydrobromide	1 in 37,500	—	—

The percentage of the alkaloid in each salt is shown in the third column of Table II, and by dividing this into the average dilution which killed all the paramoecia the relative lethal action of the different preparations on the protozoa in proportion to their quinine contents is obtained and shown in the last column. As far as this test goes, it shows that quinine bi-hydrochloride is actually, and the acid hydrobromide relatively, the most active of the quinine salts against protozoal paramoecia. Further, the acid hydrobromide of cinchonine gave slightly better results than the bi-hydrochloride. Both the cinchonine salts were weaker than the corresponding quinine ones against paramoecia, but it does not follow that they will prove less active against malarial parasites, which will be worth testing.

The Toxicity of the More Soluble Salts of Quinine and Cinchonine Intravenously in Animals.

A series of experiments was also carried out to ascertain the minimal lethal doses of solutions of these salts intra-

venously in pigeons and rabbits in strengths which would be convenient for administration in the case of man. The results are summarized in Table III.

TABLE III.—*Minimal Lethal Doses of Quinine and Cinchonine Salts Intravenously in Pigeons and Rabbits.*

Strength of Solution.	Minimal Lethal Doses in Pigeons in Grams per Kilo.			Relative Toxicity.	Minimal Lethal Doses in Rabbits in Grams per Kilo.			Relative Quinine Content.	Solubility.
	1-5	1-10	1-20		1-5	1-10			
Quinine bi-hydrochloride	0.065	0.07	0.07	1.26	0.035	0.035	2.57	0.90	1-1
Quinine urea ...	0.13	0.13	—	0.95	—	0.04	3.10	1.24	1-1
Quinine hydrochlor sulphate	0.11	0.11	—	0.90	—	0.0375	3.41	0.99	1-2
Quinine lactate ...	—	—	0.06	1.57	—	—	—	—	1-10
Quinine acid hydrobromide	—	0.13	0.13	0.94	—	0.045	2.73	—	1-7
Quinine bisulphate	—	0.12	0.12	1.03	—	0.0425	2.92	1.24	1-11
Hydroquinine hydrochlor (1)	—	0.10	—	0.90	—	0.035	2.57	0.90	1-2
(2)	0.12	0.13	0.13	—	—	—	—	—	—
Quinine periodide	—	—	0.075	2.03	—	—	—	1.52	1-20
Cinchonine bi-hydrochloride	0.07	0.08	—	—	—	0.035	—	—	—
Cinchonine acid hydrobromide	—	0.11	—	—	—	0.04	—	—	—

The minimal lethal dose in pigeons of quinine bi-hydrochloride in a solution of the strength of 1 in 100 was 0.07 gram per kilo.

A number of interesting points are brought out by the data in Table III. In the first place, it will be observed that the minimal lethal dose in pigeons of quinine bi-hydrochloride was the same, namely 0.07 gram per kilo, whether it was given in a dilution of 1 in 10, 1 in 20, or 1 in 100, but was slightly higher, 0.065, in a 1 in 5 solution. In rabbits the minimal lethal dose was the same in dilutions of 1 in 5 and 1 in 10. These observations confirm the conclusion derived from the absence of any immediate effect of strong solutions of this salt on human blood serum already dealt with, namely, that solutions of a strength of 1 in 10 may be safely injected intravenously.

The figures in Table III, giving the relative toxicity of the different salts in the case of rabbits and pigeons, have been obtained by dividing the minimal lethal doses into the relative quinine content as compared with quinine sulphate, the latter figures being given in the last column but one. Judged in this way, much the most toxic salts in pigeons were quinine periodide and quinine lactate, which I have shown above cause an immediate dense precipitate with blood serum. On the other hand, hydroquinine hydrochloride has one of the lowest relative toxicities in spite of its immediately precipitating blood serum. Possibly this is on account of its much greater solubility (1 in 2) than the lactate (1 in 10) and periodide (1 in 20). Relatively to their quinine contents quinine hydrochlor sulphate, quinine acid hydrobromide, and quinine urea gave the lowest toxicities in pigeons, and quinine bi-hydrochloride and acid hydrobromide in rabbits. I have so far only tried the bi-hydrochloride and acid hydrobromide intravenously in fever cases, and found the bromide salt can be given in from 10 to 15½ grain doses in adults without producing much dizziness, although half that amount of the bi-hydrochloride intravenously commonly produces cinchonism. In all probability the bromide radicle counteracts to some extent the action of quinine in the nervous system, hydrobromic acid having for long been used for that purpose. On the whole, the acid hydrobromide and the bi-hydrochloride of quinine appear to be the most suitable salts for intravenous injection. I had hoped to have been able to test quinine urethane and colloid quinine, but the expected supplies were lost through "enemy action."

Soluble Cinchonine Salts.

Mr. G. E. Shaw, Government of Bengal Quinologist, has very kindly prepared at my suggestion cinchonine bi-hydrochloride and acid hydrobromide, and their toxicities are also shown in Table III, while the data regarding their action on blood serum and on paramoecia have already been

given. Their toxicities are about the same as those of the corresponding quinine salts, while they are highly soluble, so appear to be suitable and well worth trying intravenously in the treatment of malaria. The acid hydrobromide salt is considerably the less toxic, but whether this combination will lessen the well known tendency of cinchonine salts to produce sickness remains to be tested. I am deeply indebted to Mr. Shaw for making these salts and also some hydroquinine hydrochloride (see (1) in Table III) for me at a time he was very short-handed.

Much of the experimental work in this paper was carried out at the Pasteur Institute, Shillong, thanks to the kindness of the director, Captain R. Knowles, I.M.S., and of Colonel H. E. Banatvala, C.S.I., I.M.S.

Suggestions for the Treatment of Malaria.

Owing to the lack of clinical material under my control at the present time I have only been able to try quinine intravenously in a very few cases of malaria, thanks once more to my friend Captain N. H. Hume, I.M.S. So far we have only given the bi-hydrochloride and the acid hydrobromide in $\frac{1}{2}$ -gram doses once a day for three or four days, but without observing more rapid disappearance of the fever and of the parasites than after quinine by the mouth, so larger doses will evidently be necessary if all the parasites are to be rapidly destroyed. As three grains of the bi-hydrochloride contain as much quinine as four of the acid hydrobromide, after commencing with $\frac{1}{2}$ -gram doses to ascertain whether the patient has any idiosyncrasy towards the drug, up to 12 grains of the bi-hydrochloride or 16 grains (approximately 1 gram) of the acid hydrobromide, in $7\frac{1}{2}$ and 10 c.cm. respectively of normal saline (making practically 10 per cent. solutions), may be given once daily for at least four days. It will probably be advisable to supplement the intravenous doses with quinine by the mouth, as the former is likely to be rapidly excreted through the kidneys—a point I am now investigating. In any case prolonged oral administration should follow the more active intravenous medication. Once the resistant relapse producing stages of the malarial parasite have been produced intravenous quinine is not so likely to be so effective, but the vigorous treatment of primary attacks of malaria by intravenous quinine appears to be worthy of careful trial to ascertain if the frequency of subsequent relapses can be reduced. Military hospitals in malarial areas should afford much more favourable opportunities for following up cases sufficiently long to enable this suggestion to be tested than civil practice. A further material advantage of such early intravenous administration is likely to be that dangerously large infections, which may terminate at any moment in fatal coma under oral administration of quinine, are likely to be rapidly controlled, and the present mortality from malaria to be reduced to practically nil.

The following is a very recent successful example of this line of treatment in the most intense malarial infection I have ever seen recovered from:

The patient was admitted at 4 p.m. in a collapsed and semi-conscious state for suspected cholera, but a low specific gravity of the blood, together with an axillary temperature of 99.4° and a rectal one of 105.6°, led to a blood examination, which revealed a malignant tertian infection of such extreme severity that a count actually showed the proportion of parasites to red corpuscles to be 46 per cent.—that is, almost one-half of them were infected. One gram of acid quinine hydrobromide in 10 c.cm. normal saline was at once injected intravenously. On the following morning the patient was conscious and much better, but the infection still amounted to 19 per cent. of the red corpuscles, so the gram dose was repeated morning and evening, and from the next morning no parasites could be found, and the patient is doing well three days later although deeply jaundiced.

Such a case speaks for itself.

Once repeated relapses have become established the only method of treatment which has given me satisfactory results is the daily administration of ten grains of quinine in one or two doses for at least three, and preferably six, months, always continuing until the end of the malarial season if in an endemic area. During the last seventeen years a number of malarial patients so treated by me have apparently lost their infections and remained free for long periods after omitting the quinine. For example, a medical man had suffered from repeated attacks of benign tertian malaria for several years, when I advised him to take ten grains of quinine a day for six months.

I saw him recently, and learnt that subsequently to that course he had remained free from fever for three years. By this plan, whenever resistant forms reproduce the fever-exciting cycle of the parasite, they will be destroyed by the continual dosage of quinine before they can multiply sufficiently to cause an actual attack of fever, and probably before they can form further resisting stages, which may thus be gradually eliminated from the system. However that may be, I believe this plan is at present the best method we have of checking malarial relapses, while it is one which should be feasible even on active service, if an abundant supply of readily-soluble quinine tablets are at hand.

THE SCABIES PROBLEM ON ACTIVE SERVICE.

BY

H. MACCORMAC, M.D., F.R.C.P.,
MAJOR R.A.M.C.(T.C.),

AND

W. D. D. SMALL, M.D., F.R.C.P.E.,
CAPTAIN R.A.M.C.(T.C.),

EVERY man incapacitated from duty—it matters not by what means—is a gain to the enemy. From the point of view of the army, and of military efficiency, those diseases ought to rank highest in importance which cause most "casualties." Judged from this aspect, diseases of the skin occupy one of the premier positions, for under the conditions of trench warfare it is inevitable that they are met with in large numbers. The exact extent of the wastage for which they are responsible is known only to the authorities, but it is apparent to all that, since many are contagious, successful efforts directed towards prevention and cure will amply repay by a very large gain of fighting men.

Of the skin diseases found amongst soldiers—excluding pediculosis—scabies is by far the commonest. When uncomplicated its effects incapacitate a man but little; but in consequence of the hard conditions of active service, secondary pyodermic complications are frequent and severe, and these are a very real cause of prolonged sickness. In contrast to the three or four days required for the complete cure of a simple case we have found that when pyodermic complications are established the period necessary is greatly prolonged—the average stay in hospital over a large number of cases being 31.67 days. It should be explained that this figure does not include either treatment elsewhere—which sometimes amounted to many weeks—or the days spent in journeying to the base.

CHARACTER AND DISTRIBUTION OF LESIONS.

Scabies as seen amongst soldiers differs in type from that usually met with in civil practice, and unless the differences are appreciated many cases will not be recognized, leading to dissemination by undetected carriers. The eruption is distributed much in the usual fashion, the sites of election being the wrists, hands, penis, lower abdomen, anterior axillary borders, elbows, and buttocks. The characteristic interdigital burrows, however, are rarely seen; they were present typically in only 13 per cent. of our cases. Vesicles are much more common, though in quite a number of cases the hands are entirely free from lesions of any sort. A correct diagnosis can only be made after inspection of the whole body. In the majority of cases the penis is involved, and the discovery of papules or crusts on either skin or mucous membrane is almost pathognomonic. This serves in doubtful cases to distinguish scabies from the acute pediculosis so frequently seen, and is for this reason an extremely useful diagnostic sign.

Besides the primary lesions of scabies, others due to secondary coccal infection are common and important. They may be so severe as to mask the primary disease

* This figure does not include cases in which one or two indefinite lesions could be found after prolonged search; including these, the percentage would be about 45. It is our impression that lately burrows have been observed with more frequency than some months ago.

and render it liable to be overlooked. Most common is a variety of impetigo distributed in a characteristic manner on the lower buttocks, elbows, and knees. The presence of pustules or crusting on one or all of these regions should at once suggest scabies and lead to search for the more primary lesions elsewhere.

Occasionally the impetigo becomes very widely spread, but even in such cases a correct diagnosis can be made by observing the characteristic grouping on the regions indicated. In numerous cases the impetigo lesion extends more deeply into the dermis and takes the form of an ecthyma. Occasionally a linear variety of impetigo is present.

Boils and other follicular infections of the skin are frequent and tend to recur indefinitely so long as the primary scabies remains uncured. No case should be considered as one of simple furunculosis until itch has been carefully sought for and excluded, or, if found, until the patient has had a thorough course of sulphur treatment.

Some degree of adenitis is the rule in all cases of scabies which have developed any form of coccal infection. The glands of the groin are those most frequently involved, and suppuration in this situation forms a not uncommon and often troublesome complication. In the upper limb severe lymphangitis with foci of suppuration seems to constitute the corresponding lesion. These septic foci usually occur in the upper third of the limb and on its inner aspect.

Dermatitis as a complication of scabies is most frequently the result of unsuitable, misapplied, or too long continued treatment. In these instances the abdomen, thighs, and arms are the commonest sites, and all degrees, from simple erythema to moist weeping or exfoliating eczema, may be observed. Subjects of the seborrhoeic diathesis seem particularly liable to this complication.

Localized dermatitis may originate in a group of vesicles or other scabid lesions, which, together with the intervening skin, have become irritated by scratching; considerable local thickening of the skin becomes superadded, and the result is an area of chronic infiltrative dermatitis, in part scabid and partly artefact. This is most commonly seen in the flexure behind the knee or on the outer aspect of the thigh.

DIAGNOSIS.

Scabies must not only be distinguished from the pyodermic conditions apt to be associated with it, but also from pediculosis, pompholyx, syphilis, and an unusual papular urticaria.

Pediculosis.

From pediculosis the diagnosis is chiefly made by the difference in distribution, and the absence of infection of hands, wrists, and penis. Not only may the two conditions be associated, but the papule common to both can only be distinguished with extreme difficulty.

Pompholyx.

The vesicular lesions of pompholyx are much more deeply seated, more numerous, and more difficult to rupture than those of scabies, and are chiefly limited to the hands and feet.

Venereal Disease.

A single large scabid lesion on the penis may give rise to question as to whether or not the patient is suffering from venereal disease, and the eruption on the body may be mistaken for a secondary rash. The diagnosis is not always so easy as might be supposed, particularly if risks of venereal infection have recently been incurred. Here also the two conditions may occur together.

Papular Urticaria.

A type of papular urticaria which we have not observed in civilian practice may simulate scabies very closely. In this condition small red papules occur over the body generally, but particularly on the abdomen and anterior axillary folds. Wheals, or some degree of dermatographia, may often be found or induced. Again, the wrists, hands, or penis are not involved, and the disease tends to disappear suddenly, while relapse is frequent.

PREVENTIVE MEASURES.

Scabies, it is generally accepted, is rarely contracted excepting after prolonged and intimate contact with infected material, for the acarus does not wander afield like the louse. This being so it is difficult at first sight to explain how the soldier gets the disease. His opportunities for removing clothing and coming into contact with an infected medium are few and are only fully possible when in rest. All the evidence, particularly the occurrence of epidemics amongst officers sleeping in the same dug-out, or amongst groups of men quartered together, points to blankets as the chief means of disseminating infection. Prevention, then, should include frequent disinfection of blankets by such a method as the Clayton sulphur vapour apparatus, or some other accepted form of sterilization. A few cases seem to be contracted from horses, and the protection of the soldier therefore includes efficient treatment of the horse. Great stress is laid by French writers¹ upon the venereal origin of scabies, and this possible source of infection requires to be kept in mind.

Of the greatest importance is the early detection of every case of scabies. Each case undetected acts as a "carrier," and is the potential starting-point of an epidemic. Frequent and thorough inspection of the individual soldier is the only means whereby early diagnosis can be assured. Infected men should be segregated and treated as speedily as possible, for, in addition to preventing dissemination, early diagnosis enables treatment to be instituted while the disease is still uncomplicated, and renders its course short, correspondingly conserving man-power.

CURATIVE MEASURES.

Curative measures should include exposure of the parasite and its ova and their destruction by remedies, short of producing dermatitis. The subsequent disinfection of clothing and bedding to prevent reinfection must never be omitted.

Sulphur, it is generally acknowledged, is the most efficient remedy for the treatment of scabies, and certainly, by reason of its procurability and cheapness, it is that most suited for the extensive requirements of an army. It is a remedy, however, which requires careful and intelligent application, and care must be taken that the patient receives neither too little nor too much treatment, the former leaving him uncured, the latter producing dermatitis, and so increasing his period of unfitness.

How this remedy should be employed is already so well known that a repetition of the details would seem unnecessary had it not been for the recent reintroduction of the sulphur vapour method. This form of treatment, so scathingly condemned by Hebra² in the first half of the last century, seems to have again obtained a certain vogue, in spite of the fact that it was so completely discredited nearly a hundred years ago. Indeed, it has so long been regarded as one of the barbarities of the dark ages that it is rarely mentioned in modern textbooks. We have had opportunity of observing a number of cases treated by this method. Some have suffered from severe dermatitis; numerous others have been uncured. The history given by some of these latter is instructive. After the vapour treatment the itching was relieved, and improvement appeared to take place in the eruption. The patient seemed cured, but after a period of about two weeks the disease again became active, so that it would appear that a false sense of security had here been obtained and a "carrier" discharged to disseminate the infection. That a certain number of cases may be cured by this method is probably correct, but its uncertainty and the special danger of dermatitis, from which it is inseparable, give us no option but to emphatically condemn its use.

Liquid preparations of sulphur, such as Fleming's solution (liquor calcis sulphurata) are undoubtedly efficient agents for the cure of scabies, but they also are particularly liable to cause dermatitis, and considerable experience is necessary for their satisfactory employment.

Sulphur Ointment.

For its simplicity and certainty, no method is so suited for general use as that of simple inunction with sulphur ointment (B.P.), and admirable results will invariably be obtained, if the treatment is conscientiously carried out and with due regard to the necessary details. It must, however, be insisted that the method of application is of

* Pediculosis as usually seen in France occurs in an acute form, and characteristically presents a papular type of eruption.

paramount importance. This may be briefly outlined as follows:

I.

On the first day of treatment the patient is given a hot bath and provided with plenty of soft soap and a large, moderately stiff nail-brush.

(a) Before entering the bath, he rubs himself thoroughly all over with the soap, massaging it into the skin, and paying particular attention to the fingers, toes, wrists, penis, and axillae. This should be continued for at least ten minutes.

(b) He then enters the bath, which should be both long enough and contain a sufficiency of water to permit of immersion to the neck. After first steeping for fifteen minutes, he scrubs himself vigorously all over with the nail-brush for the purpose of opening burrows and vesicles. If the eruption is particularly severe or painful this part of the procedure may be correspondingly modified. After the bath a final inspection should be made, when any unruptured vesicles can be opened with a surgical needle.

The bath is given with the sole object of opening up the haunts of the acarus and exposing it to the action of the parasiticide to follow. It is obvious that shower or steam baths cannot fulfil this purpose, and examination of a patient so treated will reveal the burrows and vesicles still intact.

II.

After removing the soap and drying, a liberal quantity of sulphur ointment (*B.P.*) is provided, with which the patient rubs himself vigorously all over, from the neck downwards, special attention being paid to the affected parts and to the fingers, wrists, genitals, axillae, toes, and ankles. The ointment must be liberally applied and thoroughly rubbed in, so that when finished he should be literally "soaking" in it.

The inunction is to be repeated in this manner twice daily for three days—that is, until the patient has had in all six applications. Each must be complete, and for this it is obvious that all clothing must first be removed. The treatment of limited parts of the body is useless.

III.

Finally, on the fourth day, but not before, a second bath is given, and all the patient's clothing and bedding sterilized to prevent reinfection. Even such articles as wrist-straps, strings of identity discs, gloves, etc., should be included.

The vast majority of cases, unless there be secondary complications, will be found cured after three such days of treatment. Should any doubt exist, 2 per cent. beta-naphthol in vaseline may be used daily for four more days. Only under exceptional circumstances should sulphur ointment be applied for more than three days, since its continued use is liable to cause severe dermatitis. Indeed, in susceptible persons a mild degree may be occasioned by the three-day treatment. This is usually easily cured by zinc ointment or Lassar's paste. At the completion of treatment the existence of some degree of itching is not uncommon; this is due to the remedy, and does not indicate failure of cure; it will rapidly pass off, and should be disregarded. Some days also will probably elapse before all the lesions of scabies have disappeared, although the man is no longer infective. A certain degree of pigmentation may persist indefinitely.

SUMMARY.

1. Scabies in soldiers differs in type from the ordinary form seen in civil practice, particularly in the frequent absence of burrows or other lesions upon the hands, and in the great liability to pyodermic complications.

2. The primary disease is often masked by complications. In every case of impetigo, boils, dermatitis, or inguinal adenitis, scabies must be carefully excluded before the diagnosis is considered complete.

3. Cases of scabies complicated by any of the above necessitate about ten times as long a period in hospital as simple cases, therefore early diagnosis and treatment, before secondary diseases have become established, are of the greatest importance.

4. Regular medical inspection is essential for the detection of "carriers." Infected men should be segregated and treated at the earliest opportunity; horses may also require inspection. Blankets being the chief source of spread should be sterilized as often as possible.

5. Treatment by means of sulphur vapour is a method harmful often to the patient, and at all times dangerous to the community in that it manufactures a class of scabies "carrier." In the interests of the army it should be discontinued.

6. The method of treatment most suitable to service conditions on account of efficiency, simplicity, and cheapness is inunction with sulphur ointment, but this must be carried out in a methodical and thorough manner, and with careful attention to the necessary details.

ON A CONVENIENT METHOD OF PREPARING EUSOL.

J. LORRAIN SMITH,

M.D., F.R.S.,

PROFESSOR OF PATHOLOGY;

BY

JAMES RITCHIE,

M.D.,

PROFESSOR OF BACTERIOLOGY;

AND

THEODORE RETTIE, D.Sc.,

RESEARCH ASSISTANT UNDER THE MEDICAL RESEARCH COMMITTEE.

(Report to the Medical Research Committee from the Department of Pathology, University of Edinburgh.)

Eusol may be prepared in the following way:

Take 135 c.cm. of the *B.P.* liquor calcis chlorinatae; dilute with water to 1 litre, add 10 grams of boric acid, and shake up till dissolved. The solution remains clear, and without further treatment is ready for use. If preferred, a saturated solution of boric acid may be stocked at room temperature; this contains 4 per cent. boric acid, therefore 250 c.cm. gives the amount required for 1 litre eusol. In making eusol in this way the 135 c.cm. of liquor calcis chlorinatae should be diluted to 750 c.cm. and the 250 c.cm. of boric acid solution added. This prevents the formation of the precipitate which occurs if boric acid be added to undiluted liquor calcis chlorinatae.

By this method eusol can be prepared at a moment's notice simply by diluting and mixing two stock solutions, both of which are stable.

Should eusol be required for intravenous injection in cases of septicaemia, it is necessary to add sodium chloride in the proportion of 8.5 grams to the litre. In this case, therefore, the 135 c.cm. of liquor calcis chlorinatae would be diluted to 500 c.cm. with distilled water, the 250 c.cm. boric acid solution added, and also a solution containing 8.5 grams of sodium chloride dissolved in 250 c.cm. of distilled water.

The quantities here given are calculated on a chloride of lime assaying 25 per cent. available chlorine, which is about the average obtained from commercial samples at the present time.

In our original paper¹ on the preparation of eusol we described the method of making the solution from dry bleaching powder and boric acid, and this method has been found serviceable where large quantities of the antiseptic are used and the supply has to be constantly renewed. It is less suitable where eusol is required in smaller quantities and at irregular intervals. Since liquor calcis chlorinatae keeps well, the method described above has suggested itself as a simple and convenient way of preparing eusol in any quantity desired.

Liquor calcis chlorinatae is a 10 per cent. solution of bleaching powder in water. It is therefore easily prepared, and its keeping power when tested has given the following results: In April, 1915, a bottle of the solution was made by shaking up 100 grams bleaching powder in 1 litre of water. The mixture was allowed to stand overnight and then filtered. At the time it was made it assayed 2.92 per cent. available chlorine. It was kept in a clear glass-stoppered bottle in a cupboard in the laboratory, with temperature rising in warm weather to 18° or 20° C. Over two years later, on the last day of July, 1917, the solution assayed 2.62 per cent. available chlorine; deterioration had thus taken place very slowly. A similar solution, prepared on July 1st, 1917, stored in the same cupboard during the hot weather of July, has remained at constant assay during the month—namely, 2.57 per cent. available chlorine. This solution, it may be remarked, represents a very poor chloride of lime. Generally speaking, the quality of the chloride of lime manufactured has deteriorated very much during the war.

The use of liquor calcis chlorinatae for the preparation of eusol has another advantage in that the available chlorine in the liquor can easily be determined by titration with N/10 sodium arsenite solution. The testing of the strength of the hypochlorous acid is particularly desirable when it is to be used for intravenous injection.

Standard eusol is a solution of which

- 1 c.cm. = 1 c.cm. N/10 sodium arsenite.
= 0.0035 gram chlorine.
= 0.0026 gram hypochlorous acid.

The following is an example of the application of the test where the chloride of lime is of poor quality.

Take 10 c.cm. of the liquor calcis chlorinatae; dilute to 100 c.cm. 10 c.cm. of this solution = say 0.74 c.cm. N/10 sodium arsenite solution; the end point of the reaction being determined by potassium iodide starch solution or paper. From this a simple calculation shows that 135 c.cm. of liquor calcis chlorinatae per litre is needed to give the standard eusol. When bleaching powder of high quality is used about 125 c.cm. will be found sufficient.

Sodium arsenite solution is more convenient for testing than sodium thiosulphate. Pure arsenious acid can be obtained easily, and the solution keeps indefinitely. The result is not affected by the presence of chlorates. The following method of preparing the solution is described by Cumming and Kay, and we are indebted to these authors for permission to include the description of their method in this paper.

Weigh out accurately in a small porcelain basin 1.237 grams of pure arsenious oxide (previously dried in a desiccator); add 10 c.cm. of sodium hydroxide solution (twice normal); and warm the basin on the steam bath, stirring the mixture gently until the oxide dissolves (about five minutes). Transfer the solution and the rinsings of the basin to a 250 c.cm. standard flask and add 20 c.cm. of dilute hydrochloric acid (twice normal); then add about 8 grams of sodium bicarbonate (or 100 c.cm. of a cold saturated solution), and dilute the solution to the graduation mark.—*A Text-book of Quantitative Chemical Analysis*, by Cumming and Kay. Second edition, p. 94.

Since liquor calcis chlorinatae deteriorates so slowly, a large amount of a standardized stock solution may be made at one time. Each litre of the liquor yields at least 7 litres of eusol. Further, if the test be once applied it need not be repeated till the stock has been exhausted.

A NOTE ON THE CARREL-DAKIN-DAUFRESNE TREATMENT.

By CAPTAIN R. M. ROWE, M.D., F.R.C.S. ENG., R.A.M.C.,
BRITISH EXPEDITIONARY FORCE.

The results of six months' experience of the Carrel-Dakin-Daufresne treatment in infected wounds in a general hospital, British Expeditionary Force, may be of interest. It was carried out strictly in accordance with the system employed by Carrel at his hospital. The solution, the operative technique, the appropriate number, calibre, and position in the wound of the tubes are of prime importance; indeed, the number of perforations and their size are not negligible.

The Solution.—The Dakin-Daufresne solution is rich in hypochlorite of soda, but must be neutral or alkaline. It must be tested at least every two days for free hypochlorous acid and the sample rejected if any acid be present. The solution is prepared so readily from abundant and cheap chemicals that free use or rejection is of no importance, and the method of preparation is rapid and free from technical difficulties.

Operative Technique.—Whenever possible, the wound should be converted into a broad-based crater and all damaged tissue detritus and free fragments of bone removed.

Haemostasis is most important, by ligature pressure and hot water. It is faulty technique to introduce the irrigation tubes into an oozing wound. The tubes must be inserted first into the depths and recesses, then more superficially. The tubes are made stable by fragments of one-inch web bandage removed from Dakin-Daufresne solution and arranged lightly in contact with the distal extremities of the irrigation tubes. The irrigation tubes (4 mm. calibre and 30 cm. long) are tied at the distal end

with linen thread. Perforations extend from this point for 5 cm., 10 cm., or 15 cm. along the length of the tube, so as to vary with the dimensions of the wound treated. I usually employ an open tube—that is, one not occluded by tying—for the disinfection of medullary cavities.

The Results.—The cases have in general required a longer period of treatment to secure disinfection than is the rule at Carrel's special hospitals. This is to be attributed to the later stage at which the British cases come under treatment. During the first twenty-four hours after infection of a wound smears show no microbes, although these are present in the retained foreign body—shell, clothing, etc.—from the beginning. Carrel receives and treats his cases during this aseptic period, thereby securing a more rapid disinfection process. Five days appears to be the shortest period of disinfection. This factor of delay must be kept in mind when comparing results. The majority of the cases treated by this method at this general hospital were grave wounds of the extremities with compound comminuted fractures of the long bones, often multiple, and frequently with considerable loss of substance.

Since the inception of Carrel's treatment we have found:

1. Absence of secondary haemorrhage.
2. Absence of amputations except in two classes of wounds—namely, infected wounds of the knee-joint with much bony comminution, and badly comminuted ankle-joints.
3. Septicaemia—one case.
4. Mortality—one; a very dirty comminuted knee-joint.

I may say, in conclusion, that the appearance of the patients is very striking. A clear complexion and good appetite is the rule. This immediate change in the facies of the ward gave us all—I include the nursing staff—confidence in the method long before we were justified by the accumulation of results.

THE CARREL-DAKIN TREATMENT AND A METHOD FOR ITS APPLICATION ON AN EXTENSIVE SCALE.

BY

CAPTAIN LYN DIMOND, R.A.M.C.,
BACTERIOLOGIST TO THE MILITARY HOSPITAL, HAMPSTEAD.

AND

CAPTAIN ROBERT McQUEEN, R.A.M.C.

In applying the Carrel-Dakin treatment of wounds it was found necessary that the apparatus used should be obtainable at a minimum cost, and that the labour necessary for the satisfactory carrying out of the original method should be reduced by some means.

For the individual or separate treatment of cases, a bottle (Fig. 1) was devised to replace the ampoules and apparatus recommended by Carrel in his book.

The bottle is hung upside down on a stand or prop, which can be moved to the most convenient place about the side of the bed, and is filled by means of a funnel attached to the glass tube A. The glass tube C is cut short to the rubber cork and is the means of communication with the air; the glass tube B conducts the fluid in the bottle to the wound by rubber tubing fixed with a clip. On the bottle is marked a scale in half-ounces. Every two hours when the wound is flushed, say with two ounces of fluid, the clip on the rubber tubing is released until the column of fluid in the bottle is decreased two ounces (or any other amount found necessary) by the scale.

FIG. 1.—Requirements: A wooden stand, a lib. bottle with a narrow neck, a rubber stopper (No. 5) bored with three holes, glass tubing 5 mm. in diameter, rubber tubing, one clip and one funnel.

This system works admirably for individual cases, but when the treatment must be carried out on a number of cases it requires a great amount of attention and labour day and night in order that the patients may obtain two-hourly flushes and the nurses may know the quantity of fluid each patient requires, and the necessary precautions to prevent each bottle running short of fluid.

For the treatment of a large number of patients we devised the system of bottles 2 and 3; neither need be of a greater capacity than four ounces. The system is one of siphonage with automatic flushing and refilling, so that once started no attention is required. The glass tubes A and C in these two bottles are the same, but in bottle 2 the tube B differs in that it has three bends; it produces

FIG. 2.

FIG. 3.

a siphon action, so that when the fluid in the bottle has reached a corresponding height to that in the siphon it overflows and flushes the wound. These tubes can be made of different lengths so as to give varying flushes, or this can be arranged by raising or lowering the height of the siphon tube. The various quantities of a flush should be marked on the bottles.

Into the length of tube A, which conducts the fluid from the reservoir to the bottle, is let in by rubber tubing a dropper* to regulate the number of drops required to give

Fig. 4.—Glass dropper. A, glass tubing 4 cm. long by 1 cm. diameter; B, one half of a 2 mm. glass tubing 4 cm. long slightly drawn out in a pin-head and cut in two glass tubing of sizes required in A and B can be obtained from Messrs. Baird and Tatlock, London; C, a small piece of rubber tubing passed over the end and turned back; D, a slightly larger piece of rubber tubing drawn over the doubled rubber tubing and serving to retain the dropper in its position in the glass tube; E, rubber tubing which connects dropper to the tube of the circulating system; F, rubber tubing which connects the dropper to the inlet tube of the bottle.

For the purpose of treating a larger number of patients we have devised the following system. A large reservoir

holding from 2 gallons upwards, preferably of glass (one made of papier maché could be used), is fixed at the end of the ward at a height of about 6 ft. Connected to it by rubber tubing is gas piping 7 mm. in diameter fixed round the ward behind the heads of the beds. At points in this gas piping, corresponding to the heads of the beds, are branches of smaller gas piping, about 5 mm. in diameter and 8 in. in length; to these are attached rubber tubing leading to the tube of each bottle, which is placed on the bracket about 2½ ft. above the level of the patient's body. A screw clip is placed on the rubber tubing leading from the inlet tube of the bottle to the gas piping, which is used to graduate the flow of drops from the dropper.

The end of the gas piping opposite to its connexion with the reservoir should be carried to a higher level than the reservoir, and left with an open end, so as to prevent air locks. The open end is bent in a half circle so that the opening of the gas piping is directed downwards to prevent the entry of dust into the tube.

This method requires only that the reservoir should be kept supplied with fluid. The "automatic flushing" from each bottle every two hours does not require any further supervision.

With this method of automatic flushing any number of patients can be treated without any further trouble or supervision after the requisite dosage to each patient is arranged by the regulation of the screw clip, and could be carried out easily on hospital trains and ships without interfering with the dressing of the patient, as it would require only that the tubes to the wounds be disconnected and attached again to the tubes leading from the bottles.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF INTRAURETHRAL PRIMARY SYPHILITIC CHANCRE.

The patient stated that the last exposure to infection was on January 14th, 1917 (last day of ten days' leave). He noticed a purulent discharge from the urethra on January 16th, reported sick on January 22nd, and was admitted to No. — General Hospital on January 28th, where he was detained and treated for a few days, and transferred to No. — General Hospital on February 4th.

He then had purulent discharge from the urethra in which gonococci were found. He was treated for gonorrhoea and was marked clear on March 4th.

On March 5th he reported that owing to incessant frequency of micturition he was unable to get much sleep during the night. At the same time he noticed a hard lump in the penis, about the level of the anterior part of the corona.

On March 6th he complained of pain and swelling in the right groin. This was treated with hot baths and fomentations until March 17th, but the swelling in the groin gradually got larger. On March 10th he noticed his foreskin was swelling. This gradually increased.

When examined on March 18th there was considerable non-inflammatory oedema of the foreskin, which was of a bluish colour, quite dry, and a little indurated. There was no visible sore present on the penis or in the urethra on opening the external meatus, but there was a brownish sero-purulent discharge from the external meatus.

On palpation of the penis a uniform stony-hard tender swelling of the urethra was felt, commencing half an inch from the external meatus and extending for one and a quarter inches. The swelling was approximately three-eighths of an inch in diameter. On squeezing it a slightly purulent blood-stained discharge could be expressed from the urethra. The lymphatic glands in the right groin were much enlarged, stony-hard, discrete, and painless. There was no adenitis of glands in the left groin. There were no other evidences of syphilis.

The diagnosis of a primary intraurethral syphilitic chancre was made.

A smear taken of the discharge expressed from the urethra and stained by Giemsa's method showed gonococci, spirochaetes (resembling *Treponema pallidum*), some blood and pus cells.

On examination with a small-sized urethroscope, which was passed with some difficulty on account of the pain, an ulcer was seen in the urethra. The nearer edge of the ulcer was about three-quarters of an inch, and the further edge about one and a quarter inches, from the meatus. The edge of the ulcer was sharp, well defined, and not raised above the surrounding normal walls of the urethra. The surface of the ulcer, from which a copious brownish-tinged serum could be seen exuding, was slightly depressed, and was composed of ragged, irregular, greyish-brown granulation.

A glass capillary tube was passed down the urethroscope, and a sample of the serum from the surface of the ulcer was easily collected. Examination of this serum by dark-ground illumination showed numerous active *Treponema pallidum* (twelve to fifteen to a field).

Urethral chancres are not common, and where they do occur one edge of the sore generally presents at the external meatus involving the glans penis. This case is of interest as being an example of a urethral chancre which was wholly intraurethral, and could not be seen without the aid of the urethroscope.

P. A. CLEMENTS,
Captain R.A.M.C.(S.R.).

A SCREEN METHOD OF LOCALIZATION.

THE following fluorescent screen method of using my "ladder" localizer¹ will be found very rapid and convenient.

AB and *CD* are two wires stretched across the back of the screen, at right angles to its front and back edges. The ladder is mounted in the usual way on the back of

FIG. 1.

FIG. 2.

the screen at *EF*, on the line of *AB*. Thus, with the screen horizontal, the vertical plane through *AB* includes all the wires of the ladder.

The tube is set so that the foreign body whose depth is sought is in the line of the vertical central ray, and the screen is placed horizontal and in such a position that the shadow of a chosen point of the foreign body *X*₁ lies on the wire *AB*. The shadows of all the ladder rungs are then superposed along *EF*, and the screen appearance is as shown in Fig. 1.

The tube is next displaced parallel to the front edge of the screen, so that the shadow of the foreign body moves to the wire *CD*, giving a picture similar to Fig. 2. It is clear that the depths of the foreign body and of that point of the ladder whose shadow lies on *CD* are the same.

In practice it is convenient, with a rectangular diaphragm, to expose first a narrow strip about *AB*, to verify that the bullet and ladder shadows are both exactly on that line; then to change to a narrow strip along the line of *X*₁ and *X*₂, so as to see the foreign body's shadow as clearly as possible in setting it on the line *CD*, and finally to open sufficiently to see the shadows of the ladder rungs. The wire *CD* should be mounted on an adjustable slider, so that it can be set at distances from *AB* suited to foreign bodies of very various depths.

JOHN H. SHAXBY, B.Sc., Honorary Captain,
Radiographer, 3rd Western General Hospital, Cardiff.

ABDOMINAL WOUND: FAECAL SMELLING GAS.

AMONG the series of cases of gunshot wound of the abdomen reported in the BRITISH MEDICAL JOURNAL of March 10th an instance of complication by faecal smelling gas in the subcutaneous tissue does not occur; the following case may therefore be of interest.

Pte. N. was admitted to the head quarters of a field ambulance six hours after being wounded. The entrance wound was one inch posterior to the top of the twelfth left rib. A piece of metal was felt lying subcutaneously at the mid point of a line drawn vertically upwards from the left anterior superior spine to the left costal margin. Surgical emphysema was present over the whole of the left side of the abdomen, spreading upwards over the left chest, and reaching as high as the nipple. The patient complained of great abdominal pain on the left side, and examination revealed tenderness and rigidity of that side of the abdomen. The pulse was 140, respirations 20. It was deemed advisable to operate in the field ambulance. An incision was made over the left rectus muscle; the subcutaneous tissues

were oedematous, of a dark red colour, and gave off a strongly faecal odour. Two holes in the descending colon from which faecal matter was escaping were stitched up. The patient recovered from the anaesthetic, but died six hours later. Pressure of work prevented a post-mortem examination being made.

Two suggestions as to the cause of the faecal smelling gas occur: (1) Gas gangrene with superadded *B. coli* infection; (2) escape of intestinal gas from the colon into the subcutaneous tissues.

C. S. STADDON,
Captain R.A.M.C.(S.R.).

British Salonica Force.

LUMBAR HERNIA.

LUMBAR hernia is stated to be comparatively rare; perhaps it is on this account that the textbooks do not give detailed descriptions of the sac as they do for other forms of hernia. The sac has been found on dissection to have been reduced along with the contents. A rare form of "sacless" inguinal hernia of the caecum is described. The following case, in which there was no peritoneal sac, may therefore be worthy of record.

C., a male of the Tonga tribe, aged 55, presented himself with a swelling in the left lumbar region. History and symptoms are not easy to get from natives, but this man volunteered the information that the swelling developed as the result of a fall, and that it gave him pain at the seat of the lesion, and also caused pain and a dragging sensation in the corresponding region on the right side. He was found to have a left lumbar hernia through the triangle of Petit, which protruded to the size of a large fist on coughing. Radical cure was undertaken.

The operation was performed under spinal anaesthesia, the patient lying on the left side with the hips raised two inches; five grains of stovaine were injected through the third lumbar space, the patient was then turned on his back for a minute or two, and then on his right side, with a pillow under the loin. The skin and fascia were divided by the oblique lumbar colotomy incision, the external oblique pulled forward, and the triangle of Petit exposed. Lying in this space there was a quantity of loose areolar tissue and masses of subperitoneal fat. This tissue being picked up search was made for a sac, but none was found; as the dissection progressed there was pulled up through the hernial aperture a loop which from its consistence appeared to be bowel, but no sac had been opened, and the bowel had no peritoneal covering; a finger passed through the opening in the abdominal wall entered a kind of false cavity, but not the general peritoneal cavity. Lest there might be an adherent sac, which might be reduced *en masse* with its contents, an attempt was made to strip the outer coat, but it was at once apparent that it was the coat of the bowel which was being stripped. The question was definitely settled by a small incision into the bowel and the appearance of faeces. The opening into the bowel was closed, and the fibrous covering stitched over it; then the loop of bowel, which could not be pulled out far into the wound, was reduced within the abdominal cavity, redundant masses of subperitoneal fat were removed, and the stumps introduced within the opening to serve as a pad on the inner face. The aperture, less than two fingerbreadths wide, was closed by a mattress suture, muscles and fascia were brought together, and the skin incision closed. Slight sensation returned as the cutaneous stitches were being introduced. The patient made an uninterrupted recovery.

Sac.—It would appear that the descending colon was not completely covered by peritoneum, and that the hernia was from the posterior uncovered portion; thus the peritoneal sac was absent. In the movements of protrusion and retraction the bowel must obviously have loosened its fibrous connexions to the abdominal wall, and this would account for the false cavity felt on introducing the finger.

Closure of the Aperture.—Owing to the fibrous nature of the edges, and their tendinous attachment to the crest of the ilium, difficulty was experienced in closing the aperture as the edges would not approximate, and there was a tendency to tearing or splitting of the aponeurosis by the suture. It might have been possible to make use of some fibres of the quadratus lumborum to close the opening, but this was not attempted.

WM. Y. TURNER, M.B., Ch.B.

Livingstonia Mission Hospital,
Bandawe, Nyasaland.

In his annual report for 1916, Dr. F. W. Alexander, M.O.H. for Poplar, refers to ophthalmia neonatorum and its notification, a subject to which he has devoted much attention during recent years. In his report for 1910 he urged the compulsory notification of this disease. Since February, 1914, notification has been compulsory in every sanitary district of England and Wales. In Poplar upon the receipt of a notification the case is immediately visited by a health visitor, and is kept under constant observation; if necessary the services of a nurse are procured from one of the nursing associations working within the borough.

Rebuelus.

THE CAUSES OF TUBERCULOSIS.

THE records of experimental research into the life-history and variations of the tubercle bacillus have become somewhat overwhelming in quantity during the last decade. Certain general conclusions have emerged from them, but without that careful weighing of all the evidence which is essential before a fair judgement can be formed. Himself a well-known research student and teacher, Dr. Louis COBBETT of Cambridge has recently set forth at great length, in a bulky volume of over 700 pages, entitled *The Causes of Tuberculosis*,¹ the whole story of modern experimentation, indicating clearly those points which may now be regarded as settled, and contrasting them with the far larger sum of those which require more positive proof than they have yet received. Although his work covers a much larger field, still the main interest to the medical profession turns upon the much discussed question of the relations of the bovine to the human type of the disease. The result of a long and elaborate discussion of the problem, and very careful examination of the evidence upon which his conclusion rests, leads the author to lay down very definitely the view that it is during the first five years of life that the real danger of infection by the bovine type exists. With each succeeding period the liability to such infection grows less and finally disappears with adult years. The obvious deduction from this verdict points directly to raw milk as the carrier of infection. The danger from the ingestion of infected meat is practically negligible, since it is almost invariably sterilized by cooking. These facts are not new. The danger of raw milk has been made known to every one, but the absence of any direct and recognizable evidence of such danger continues to lead to the daily and hourly exposure of infants and young children to the disease which may cut short their lives in the course of their first five years. The tuberculous disease of infancy is not always bovine, and there may be many other channels by which the bacillus can find means of entry, but the bovine type prevails in sufficiently large proportion to call for drastic measures for prevention.

Very careful observations have been made as to the possible conversion of the bovine bacillus to the human type while in the human body, but it seems to be proved that the type remains constant and that the bovine form, recovered from the human subject, retains its former virulence for susceptible animals such as the calf, the goat, or the rabbit, all of which are but little influenced by the presence of the human type.

In the vast multitude of experimental observations which are recorded or referred to in Dr. Cobbett's book, it must happen that errors, leading to puzzling and sometimes contradictory results, creep in, but they are for the most part accounted for by the ever-present risks of accidental infection where large numbers of animals are kept in confinement under laboratory conditions. The relations of the bovine type of the disease to a great variety of animals have been most carefully investigated, and the evidence thus accumulated will prove of the greatest value to every one who may have to deal with tuberculosis in zoological and other collections.

The whole etiology of the disease as it affects the human subject is most carefully analysed. The main conclusion to be drawn from it differs somewhat from a widely accepted opinion as to the relative importance of the bacillus and the soil in which it flourishes respectively. Dr. Cobbett considers that the main danger lies in the size of the dose of the poison rather than in the degree of susceptibility of the recipient. Holding this view, it is natural that he should place the segregation of the advanced case in the forefront of any scheme for suppression of the disease in communities. It is highly probable that massive infection is brought about mainly by the agency of the advanced and disintegrating disease in the human lung. Segregation on a large scale is not possible under present conditions, but might well be put in force to a far greater extent than it is without legislative compulsion.

¹ *The Causes of Tuberculosis*. Together with some Account of the Prevalence and Distribution of the Disease. By Louis Cobbett, M.D., F.R.C.S., University Lecturer in Pathology, Cambridge. Cambridge Public Health Series. Cambridge University Press. 1917. (Med. 8vo, pp. 707. 21s.)

Such a work as Dr. Cobbett's supplies a want, containing as it does the cream of modern knowledge on the subject of tuberculosis, presented in a form which is at once interesting and convincing. A full index and a concise summary of each section of the subject under discussion, renders it easy of reference. The photographic illustrations of the disease in various types of animals are excellent, and add considerably to the practical usefulness of the whole treatise.

ON TWINS AND TWINNING.

WHETHER it be from motives of economy, or as an offset to its unapproachability, or whatever be the cause, the "modest and retiring" armadillo of Texas, with its nine zones of body armour (*Dasypus novemcinctus*), is distinguished above other animals by the fact that from a single fertilized ovum it habitually gives birth to four young. And these four young are "identical" and invariably of the same sex. It is around the study of this phenomenon, which he and Dr. J. T. Patterson have continued for the last eight years, that Professor H. H. NEWMAN, now of the University of Chicago, has built up a useful volume on *The Biology of Twins* in the Science Series of that university.² The volumes of this series differ from the discussions generally appearing in technical journals in that they present the complete results of an experiment, or series of investigations which, if published at all, have previously only appeared in scattered articles. They differ from detailed treatises by confining themselves to specific problems of current interest, and in presenting the subject in as summary a manner and with as little technical detail as is consistent with sound method. Professor Newman's little volume fulfils excellently these aims. He has brought together the observations of himself and others contained in many scattered papers upon the polyembryony of *Dasypus* and allied forms, and describes the embryology of the condition in studiously clear and simple language. With this as a basis, he proceeds to discuss the biology of twinning as it occurs in man and other mammals. As is by now generally acknowledged, among animals which usually produce single young, two orders of twins, triplets and quadruplets may show themselves, namely, the production of paired or plural offspring from plural eggs (*fraternal twins*), and the production of paired or plural offspring from a single fertilized egg or zygote (*duplicate twins*). As to the relative frequency of these two orders in man, the author quotes the analysis by J. B. Nichols, of some 700,000 cases of twin births, from which it appears that "nearly one-half of all same-sexed twins are monozygotic." Such twins are strikingly like each other, are always of the same sex, and, as Professor Wilder has shown, the identity extends to the palm and finger-print patterns, although here, curiously, whereas in some cases there is an almost complete mirror imaging of the two palm patterns of the two individuals, the left hand of *y* corresponding to the right hand of *x*, in other cases this reversal occurs to only a limited extent, but then always in connexion with the pattern of the index fingers. Newman demonstrates a parallel condition in connexion with the bands of armour of the armadillo, the first band taking the place of the index finger in man; and as the demonstration is absolute that in the Texan armadillo the twinning is monozygotic, any last doubts as to the existence of monozygotic twins in man must disappear.

Newman shows clearly that the four embryos in *Dasypus* do not originate each from one of the four primary blastomeres of the fertilized egg; nor does he accept Assheton's theory of budding. His preparations point to a fission or duplication of the apical point of the growth zone, with formation of secondary growing points as the cause of twinning, that is, to the origin of these monozygotic twins at a period when some differentiation has occurred in the embryo, so that the twins are not of necessity absolutely identical in each detail.

One of the most interesting chapters in the book is that upon the "freemartin" which, ever since John Hunter, has been a source of keen discussion. Newman rejects Dr. Berry Hart's Mendelian hypothesis, holding that it is

² *The Biology of Twins (Mammals)*. By Horatio Hackett Newman. Chicago: The University of Chicago Press. 1917. (8vo, pp. 179, with index. 1.25 dols. net.)

based on error, since bovine twins are not monozygotic. Bateson seems to have fallen into the same error. Professor F. R. Lillie has recently solved the mystery by a study of abundant material obtained from the Chicago stockyards (*Science*, N.S., 43, 1916). He shows that in cattle a twin pregnancy is almost always the result of fertilization of an ovum from each ovary. When these are of different sexes and there is fusion of the two chorions *in utero* with vascular anastomosis, since the male reproductive organs develop earlier than the female, the reproductive system of the female is largely suppressed, apparently as the result of antagonistic hormone action due to the circulation of the male blood in the female, whereby the latter becomes and remains sterile from arrested sexual development. "The results are analogous to Steinach's feminization of male rats, and masculinization of female rats by heterosexual transplantation of gonads into castrated infantile specimens."

Altogether the work is of sustained interest and represents a distinct advance in knowledge.

AFTER-WAR PROBLEMS.

IN a volume entitled *After-War Problems*,⁸ the editor, Mr. WILLIAM HARBUTT DAWSON, has brought together a number of essays, written by well-known authorities, on problems which the country will have to face in the altered social situation produced by the war. "The ordeal which the nation has been called to face," says the editor in his introduction, "has evoked an outburst of moral energy without parallel in the history of the British race. Shall the moral forces now in action be demobilized in county and city, in town and hamlet, when the struggle is over?" The articles which follow indicate from widely different points of view how these forces may be preserved and developed for the benefit of the national life. For the sake of convenience the subjects are divided into four broad groups: the first is "Empire and Citizenship," and the authors are the late Lord Cromer, Bishop Welldon, Lord Meath, and Sir H. H. Johnston. The second group, entitled "National Efficiency," contains papers on industrial problems, and the relations between capital and labour, by Dr. W. Garnett, Professor S. J. Chapman, Mr. G. H. Roberts, and Sir Benjamin Browne, together with papers on the land question by Mr. Joynson-Hicks; on the position of women in economic life, by Mrs. Fawcett; on the organization of the national resources, by Sir J. Compton Rickett; and an article by Lord Haldane on national education. The third group—closely related to the second—is headed "Social Reform," and here the medical reader will find matter of special interest to him. Two papers, one by the Bishop of Exeter and the other by Mr. H. R. Aldridge, glance at the housing problem from two distinct aspects. Dr. James Kerr contributes a chapter on national health, in which he argues that beyond what has been done there remain vast possibilities for improvement if the conditions are squarely faced and firmly dealt with. Whilst convinced that all services and commodities necessary for public health should be completely controlled by the community, Dr. Kerr is opposed to the idea of a State service of medicine, which, he says—with a good deal of truth—finds little professional support beyond the officials themselves. Again, in advocating the need for securing the best men as medical officers of health, he knocks aside the notion that the medical officer of health as a kind of professional superman could be otherwise than repugnant to those with actual clinical experience, in which the mental factor plays so great a part. To his mind a general State service of medicine, controlled by bureaucratic supermen, would have a "sterilizing and deadening effect, in which schedules would soon be likely to be more thought of than patients. The true function of a State department in science or medicine is to collate knowledge and distribute advice." Other chapters in this section deal with the care of child life, from the pen of Miss Margaret McMillan, and with unsolved Poor Law problems, contributed by Sir William Chance. The last group contains articles on national finance and taxation, by Professor Alfred Marshall and Mr. Arthur Sherwell.

Taken as a whole, this volume of essays will be found stimulating to patriotic thought and endeavour. To quote once more from the introduction: "Only by the cultivation and co-ordination of all her intellectual and moral forces and vitalities will England come through her final ordeal triumphantly."

INDIAN HYGIENE.

THE importance of teaching the laity the principles and practices upon which the preservation of health depends has been increasingly recognized in India within recent years. Many excellent treatises on hygiene have been published for both general and special use. Among these McNALLY'S *Sanitary Handbook for India*,⁴ of which a fifth edition has recently appeared, holds a high and useful place. Originally published in 1889, it was "addressed primarily to the educated classes and through them to the great uneducated masses of the people, and intended as a guide to personal, communal, and public sanitation." That it has fulfilled its purpose is attested by the fact that "it has become one of the recognized textbooks for the students in the Medical College and for the classes of sanitary inspectors." Written by an officer of the Madras Medical Service, the book, while expounding conditions affecting health in tropical and subtropical countries generally, has special reference to those prevailing in the Madras Presidency. In successive editions careful revision has kept pace with advancing science and accumulating experience. The present (fifth) edition has been ably brought up to date by Captain A. J. H. RUSSELL, who has added an important chapter on Insects and Disease, a subject of very great consequence in tropical countries. The book is well arranged and indexed, and the various topics usually treated of in hygienic manuals are clearly and instructively set forth in language well within the comprehension of those for whose use it is intended. Diagrams and plates, which are stated in the preface to the third edition to have been both "crude and out of date," are omitted. The Madras City Municipal Act, which is very exhaustive, is reproduced *in extenso*. The Madras District Municipalities Act, which embraces all appropriate and necessary sanitary regulations, and the sections of the Indian Penal Code and the Code of Criminal Procedure which relate to public health, are also cited. Altogether this volume is well adapted to fulfil its purpose of instructing the inhabitants of Southern India regarding sanitary perils, precautions, and duties.

"WHAT EVERY WOMAN SHOULD KNOW."

THAT it requires a past master on the subject to write an elementary book is borne in on the reader of some simple and charming lectures given by Professor CHARLES RICHEL⁵ to the French Red Cross helpers on antiseptics, anaesthetics, foods, haemorrhage, fever, and asphyxia. Thanks to antiseptics, the mortality among the wounded, which in bygone days was 80 per cent, or even more, has now fallen to 5 per cent. Four periods of chloroform intoxication are described—(1) analgesia or death of the psychical system, (2) anaesthesia or death of reflex actions, (3) death of the medulla with cessation of respiration, and (4) death of the cardiac nerve cells with syncope and general death. The fatal course of asphyxia runs through the same stages as chloroform intoxication, and an emphatic direction is given always to try artificial respiration, as the heart beats may be so feeble as to be imperceptible. In speaking of local anaesthesia, Professor Richet mentions that in 1855 his father recommended ether for this purpose. In the lecture on foods the calorie value is lucidly explained, and life is defined as the cell's consumption of protein. The descriptions of haemorrhage, fever, and asphyxia are supplemented by brief summaries of the appropriate treatment. The author concludes his genial account of her necessary qualities by remarking that, although the ideal nurse must be superhuman, in practice less must suffice, and that the essential attribute is kindness of heart.

⁴ McNally's *Sanitary Handbook for India*. Fifth edition, revised and rewritten by A. J. H. Russell, M.A., M.D., Ch.B., D.T.M., Captain I.M.S. Madras: Government Press. 1916. (Demy 8vo, pp. xv + 414, 3s. 9d.)

⁸ *After-War Problems*. By the Earl of Cromer and others. Edited by W. H. Dawson. London: G. Allen and Unwin, Ltd. 1917. (Demy 8vo, pp. 366. 7s. 6d. net.)

NOTES ON BOOKS.

DR. DAWSON'S *Elements of Anatomy and Physiology for Nurses*⁶ is an excellent book in which the two sciences, usually kept apart, have been skilfully fused into one. It is clearly written, and contains not too much information for the instruction of those for whom it has been composed. It contains, too, a number of excellent illustrations and diagrams; perhaps the student would gain if the magnifications of the microscopic reproductions were inserted. The book may be warmly recommended to both nurses and their instructors.

Vol. III of the *Bombay University Calendar for 1916-17*⁷ contains lists of graduates of the university, a catalogue of its 113 several endowments, and an account of the benefactions it has received. Particularly to be commended is the confidence in the future which prefaces this volume with the observation, "Published every tenth year. The next publication of this volume will be in 1926."

The morality of the public administration in Mexico is not all it should be. *Salus populi suprema lex*, and Mr. A. J. PANI⁸ has written an interesting and well documented volume in which he indicates the many opportunities for improvement in the action of the Mexican sanitary and educational authority. Mr. Pani is a Carranzist, and writes not only as a Carranzist but also as an expert in sanitation and public works. He makes out a good case for the reforms he indicates as urgently necessary even in Mexico City, the most civilized portion of the Federal District. Mr. Pani's political party is now in power, and, as he clearly shows, it has a great opportunity for social amelioration before it.

The *Calendar of the University of Toronto*,⁹ so far as concerns its Faculty of Medicine, is a brief manual containing the information usual in these works of reference. This year, however, it contains a note of more than usual import and moment to the medical student: the Senate of the University of Toronto has determined to increase the length of the undergraduate course in medicine from five to six years, after the close of the war. From the European standpoint it is, perhaps, fortunate that no medical student is likely to be consulted as to the precise date when such a regulation shall become operative.

MEDICAL AND SURGICAL APPLIANCES.

A Pneumatic Tourniquet for Surgical Purposes.

MR. G. GREY TURNER, M.S. (Newcastle-on-Tyne), writes: For some years I have endeavoured to procure a satisfactory pneumatic tourniquet and have experimented with several patterns, home-made and otherwise, but with only partial success. I now find that the initial mistake was in supposing great pressure to be necessary and in endeavouring to devise an apparatus sufficiently strong to withstand it. A few experiments with "Harrison's pneumatic armband" soon convinced me that no greater

pressure than could be procured by the simple hand bulb of that instrument was necessary, and indeed, with only slight modification, this apparatus makes an excellent tourniquet. To make it efficient for surgical purposes I found it necessary to introduce a clip (A) between the valve and the pad, otherwise enough air escapes to render the tourniquet ineffective within a short time. It is also necessary to use a strap and buckle with loops, to prevent the pad getting out of position when fully inflated, and I have found it an advantage to have the inner surface of the pad covered with soft wash-leather. To get the

best results with any type of tourniquet, the limb should be first emptied of blood, and this is best attained by the application of a rubber bandage after Esmarch's method. The tourniquet is then applied round the limb at the required site, the leather-covered surface being in direct contact with the skin. When compression is desired it is inflated as rapidly as possible by vigorous pressure on the bulb. As soon as no more air can be got to enter, the clip (A) is tightened and the circulation will be found to be completely arrested. Should it be necessary to relax the compression during the course of the operation this is easily done by releasing the clip and the valve, but when it is to be reinflated care must be taken to do so rapidly, and, of course, the result cannot be so good as when the limb has been first exsanguinated. It is necessary to have a longer pad for the thigh in adults, and it will be found convenient to use two sizes, the original armband for the upper extremity, and for the lower extremity in children, and the larger size for the latter purpose in adults. In actual use the apparatus has proved thoroughly efficient and reliable. The Holborn Surgical Instrument Company, Ltd., are the manufacturers and have adapted the pneumatic armband of Lieut.-Colonel Harrison for the purposes of a surgical tourniquet very satisfactorily.

A Double-barrelled Syringe.

MR. J. E. R. McDONAGH (London, W.) writes: This double-barrelled syringe is made in two sizes—one to hold two cubic centimetres and the other to hold twenty cubic centimetres. The object of the smaller syringe is to inject a little saline from one barrel after the drug has been injected intramuscularly from the other barrel, and so prevent a track being made during the withdrawal of the needle. The mercury, or other drug, is thus prevented from getting into the subcutaneous tissues and producing an abscess or an indurated lump. A local anaesthetic can be given before the drug is injected intramuscularly, without having to make two pricks. The larger syringe is for intravenous or for intraspinal work. If the left barrel, to which the needle is attached, is filled with the solution to be injected, after inserting the needle into the vein, blood may be withdrawn into the right-hand barrel and emptied into a receptacle as often as desired, before or after the drug is injected. When injecting colloids, it is a good plan to let the blood mix well with the colloidal suspension before it is injected, a manoeuvre which can be well carried out with this double-barrelled syringe. As the right barrel can always be filled and refilled with a solution from a receptacle underneath, and the contents discharged into the left barrel, a dilute as well as a concentrated intravenous injection may be given. Another advantage is, that the right-hand barrel may be filled with a calcium chloride, glucose and gelatin mixture, which can be injected through the same needle before the contents of the left-hand barrel are discharged, to prevent shock, or after, should symptoms of shock threaten. The syringes can easily be sterilized because the glass can be boiled separately from the metal casing by merely unscrewing the cap to which the piston is attached. They are made by Allen and Hanburs, Limited, 48, Wigmore Street, London, W.1.

A COMMITTEE on war psychology has been formed by the United States Research Council with the approval of the American Psychological Association. Twelve special committees have been appointed to deal with various questions of war psychology, and the chief psychological laboratories of the States have offered their services. Among the problems to be studied are those of shock, emotional stability, fear, and self-control, of re-education and vocational training, of recreation, and of military training and discipline.

A COMMITTEE on industrial fatigue has been formed under the advisory commission of the United States Council of National Defence. The committee is investigating munition factories and other establishments manufacturing war supplies, with the object of showing how avoidable fatigue may be eliminated, and how the great output of war material may be obtained consistently with maintenance of the working power of those employed. The chairman of the committee is Dr. Thomas Darlington of New York, and Professor Frederic S. Lee, Columbia University, is executive secretary.

British Medical Journal.

SATURDAY, SEPTEMBER 22ND, 1917.

CEREBRO-SPINAL FEVER AND ITS TREATMENT.

It is generally recognized—*pace* Dr. Hort and the new meningoascus he describes, in the JOURNAL this week, with microbial forms in many ways comparable to the bacterial gonidia of Löhnis and Smith—that the intracellular meningococcus discovered by Weichselbaum in the year 1897 is the infecting agent in cerebro-spinal fever, and it has long been known that various types of this microbe are met with in epidemics of the disease. From the laboratory point of view several different strains or races of the meningococcus have been recognized and differentiated by their immunological reactions; indeed, forms have been described so different from one another as to deserve the name “subspecies.” The matter is one of great importance from the clinical point of view, and for this reason. The most promising line of treatment in cerebro-spinal fever consists in the administration of the specific antiserum. Experience has shown that the results of treatment with our present antimeningococcal serums have generally been disappointing. The reason for this lies, no doubt, in the fact that the samples of this serum employed have been derived from different types or strains of meningococci in very many instances, and not from the particular type present in the patients under treatment with these particular serums. In other words, there have been many cases in which the “specific” antimeningococcal serum has not been specific for the individual infection against which it has been employed; and so, naturally, it has failed. Practical means for differentiating the various types of meningococci have long been sought, and the recent work of Lieut.-Colonel M. H. Gordon, Mr. E. G. Murray, and Captain W. J. Tulloch¹ goes to show that the differential absorption of agglutinins by the microbes of these various types may afford us the necessary means of distinguishing between them in cases of cerebro-spinal fever. The credit of having placed the whole question on a satisfactory basis belongs to Lieut.-Colonel Gordon. Defining as the meningococcus any Gram-negative diplococcus that causes primary meningitis, he proceeded to investigate the relations existing between them by agglutination, using as material the organisms isolated from the cerebro-spinal fluid of cases of the disease. In the first instance he worked with three such organisms, and with fourteen meningococcus-like organisms isolated from the nasopharynx. His second paper, written in conjunction with Mr. E. G. Murray, dealt with thirty-two further specimens of the meningococcus, and nine more Gram-negative cocci indistinguishable from it by cultural and fermentative tests, isolated from the nasopharynx of contacts or of cases of suspected cerebro-spinal fever. The third paper, written by Captain W. J. Tulloch, summarizes the whole matter, and is based on the examination of 107 strains of the meningococcus. By means of exhaustive tests of their

agglutinating powers it has been found possible to refer all but six of these separate strains to four main types. The agglutinating serums used were obtained by inoculating rabbits with the specific strains of meningococci isolated from spinal fluids. A standardized technique was employed, and is described in detail; it is a matter of some complexity, and depends upon the ability of a meningococcal emulsion to saturate its specific agglutinin, leaving any other agglutinins that may be present in the agglutinating serum more or less unaffected. The general result of these investigations has been to show that out of 101 different strains of meningococcus thus classified, 30 belong to Type I, 41 to Type II, 13 to Type III, and the remaining 17 to Type IV. It should be added that Type II is apparently a complex subgroup, and that there are considerable variations in the behaviour of its individual members on agglutination.

The important bearing that the discrimination of such types of meningococci has upon the treatment of cerebro-spinal meningitis is obvious. If we have an epidemic of the disease produced by a group of organisms, each member of that group should have its specific antiserum; alternatively, a polyvalent antiserum should be prepared for the broadcast treatment of the epidemic. Captain Tulloch suggests that polyvalent antimeningococcal serums should be richest in the antibodies produced by cocci of Types I and II, which seem to occur most often; the ideal method of treating any given case of the disease would be to administer the polyvalent serum in the first instance, when lumbar puncture is performed for diagnosis, and as soon as the type of the infecting meningococcus has been ascertained in the laboratory to continue the treatment by injecting the appropriate specific antiserum. This new classification of meningococci into four main types has also an important bearing on the administrative control of cerebro-spinal fever from the point of view of public health, because it should enable us to draw a clear distinction between true meningococci and the meningococcus-like organisms that are found so often in the nasopharynx that are not pathogenic and may be called pseudo-meningococci. From 6 to 7 per cent. of meningococcus carriers were found in a total of over 10,600 contact cases examined in 1915, some observers even finding as many as 20 per cent. Captain Tulloch proves that as many as 50 per cent. of these carriers may be harbouring only the pseudo-meningococcus; such carriers, of course, require neither treatment nor isolation.

It seems hardly necessary to labour the point that the treatment of cerebro-spinal fever is capable of much improvement by the discovery of truly specific antisera. Additional evidence on this point, however, is furnished by a recent report² on the disease as it occurred in Australia in epidemic form during the year 1915. The report is based on a personal experience of over 450 cases of cerebro-spinal fever treated in the Melbourne and Alfred Hospitals during the epidemic in the State of Victoria; in all there were 644 cases reported, with a mortality of 52 per cent. The authors give a very full account of the methods of treatment employed. They emphasize the point that the best treatment now available consists in the repeated hypodermic or intravenous or intrathecal injection of antimeningococcal serum, using relatively large doses. For intrathecal injections the dose should be about 30 c.cm.; but the patient should

¹ *Journal of the Royal Army Medical Corps*, London, 1915, xxiv, 455; xxv, 411; and 1917, xxix, 66.

² *Cerebro-spinal Fever*. By N. H. Fairley, M.B., B.S., and C. A. Stewart, M.B., B.S. Service Publication No. 9 of the Quarantine Service of the Commonwealth of Australia. Melbourne, 1916.

receive about 200 c.cm. of the serum daily for several days if he is seriously ill, and in all severe cases the initial dose should be 300 c.cm., administered subcutaneously. Whether intrathecal injections of the serum are given or not, lumbar puncture and the removal of 50, 70, or even 100 c.cm. of cerebro-spinal fluid are to be performed daily. As regards the use of anaesthetics here, the authors say that in small children and very occasionally in adults who cannot be restrained, and might cause breakage of the needle, a general anaesthetic may be given, and chloroform is satisfactory. But they add that general anaesthetics are most undesirable here, and should not be given except for the best of reasons; some local anaesthetic may be used at the site of puncture. On this point the authors are in disagreement with Major Michael Foster and Captain J. F. Gaskell,³ who strongly recommend the use of general anaesthesia when lumbar puncture is performed. Discussing the results of the serum treatment, Drs. Fairley and Stewart tabulate 131 cases of cerebro-spinal fever treated with injections of normal horse serum, with a mortality of 50 per cent.; 75 cases treated with antimeningococcal serum, mortality 45 per cent.; and 34 cases treated by lumbar puncture only, mortality 56 per cent. Excluding cases either moribund on admission or over 35 years of age, the three above mortalities worked out at 47, 33, and 26 per cent. respectively; only the fairly mild cases were treated by simple lumbar puncture. It is remarked that the use of antimeningococcal serum quickens the process of recovery and lessens the percentage of acute cases that become subacute or chronic.

A further improvement in the serum-therapy of cerebro-spinal fever consists in the intrathecal employment of antimeningococcal serum reinforced by the addition of human serum taken from convalescent cases of the disease. It is known that cerebro-spinal fever is deficient in antibodies of all sorts, particularly complement; the notion underlying the employment of this reinforced serum is that the human serum added will contain complement, and thereby render the bacteriotropic action of the antiserum more effective. The improved results of this line of treatment are said to be very promising, but not yet (as it is in its infancy) statistically demonstrable. As a rule 5 c.cm. of human serum were injected, together with 20 c.cm. of antimeningococcal serum.

As for other methods of treatment, Drs. Fairley and Stewart recommend the daily washing out of the theca with normal saline, thrice repeated, before the antiserum is injected, in cases where the cerebro-spinal fluid has become thickly purulent and tends to block the needle. The headache and delirium of the acute stage should be treated by lumbar puncture, and by the exhibition of 20 grains of aspirin, combined with ten minims of liquor morphinae hydrochloratis in half an ounce of chloroform water. All subacute and chronic cases of the disease are placed on a vaccine prepared from several stock cultures—here we seem to see the need of some differentiation of the various types of meningococci described by Captain Tulloch—administered in doses increasing from 500 million to 6,000 million microbes, at intervals of four days. The operative treatment of the disease, apart from lumbar puncture, is considered at some length, and the authors conclude that the sudden respiratory failure and death which may occur in the acute stage of the disease are due to acute cerebral hyperaemia, and not, as is commonly thought, to acute hydrocephalus, and are best treated by venesection. The onset of this respiratory failure may

be anticipated if the patient becomes deeply flushed, very restless and delirious, and has intense headache not relieved by lumbar puncture. Ventricular puncture and decompression by trephining were found to be useless in this condition; on the other hand, these operations were performed in nine subacute or chronic cases with signs of internal hydrocephalus. All terminated fatally, but in several instances the patient's life was prolonged. It is noted that three out of nineteen cases of internal hydrocephalus recovered spontaneously. In the final chapter of the report the use of urotropin and helmitol as cerebro-spinal antiseptics is considered in detail. In the absence of adequate supplies of antimeningococcal serum in the early days of the epidemic urotropin was thus used extensively. The authors conclude that both clinically and experimentally it is useless as a cerebro-spinal antiseptic. It can liberate formaldehyde only in an acid medium, and cerebro-spinal fluid is always alkaline; urotropin itself is not an antiseptic agent. The report on helmitol is more favourable. Helmitol, or hexamethylene tetramine anhydromethylene citrate, liberates formaldehyde in alkaline as well as in acid media; *in vitro* it does inhibit the growth of the meningococcus. But it has not proved possible to discover formaldehyde in the cerebro-spinal fluid even after massive intravenous injections of the drug, perhaps in consequence of lack of delicacy of the chemical tests employed for its recognition.

MEDICAL EXAMINATION UNDER THE NATIONAL SERVICE SCHEME.

SIR AUCKLAND C. GEDDES, Minister of National Service, in his statement on September 15th on the general policy of recruiting and the organization of the Ministry of which he is the head, indicated the broad lines upon which the medical department will work.

In the office of the Ministry, with direct responsibility to the Minister, there will be a Chief Commissioner of Medical Services. It is intended also to establish an Advisory Medical Board which will advise the Minister on medical subjects generally, including such specific points as the arrangement of standards for determining the grades of physical efficiency. It is hoped also that a smaller Advisory Board will be attached to the Deputy Commissioner of Medical Services in Scotland, with Edinburgh as the administrative centre. The whole country will be divided into ten recruiting regions, each of them with a Deputy Commissioner of Medical Services and a Director of Recruiting. The Deputy Commissioner for each region will be responsible for the general policy and conduct of the examinations to be conducted by the medical boards throughout his region, carrying out the policy of the Ministry under the control of the head office in London. Each region will be divided into recruiting areas. In each area there will be one or more medical boards, presided over by presidents. The members of the medical examining boards will be appointed from among the medical men of the area considered suitable for such work on account of their professional knowledge and position; they will serve on a rota and will receive remuneration, the amount of which will be governed by the time given to the work. It is hoped to obtain for the office of president of each board a medical man with recent experience of the conditions of military service. The Ministry will be aided in the selection of medical men to serve on the boards by the professional committees acting through the Local Medical Committees throughout

³ See BRITISH MEDICAL JOURNAL 1916, vol. i, p. 592.

the United Kingdom. Care will be taken that the examination and, if necessary, re-examination of men by the medical boards of the Ministry will be as thorough and complete as possible. After examination by these boards a man will still possess the right of appeal on medical grounds if he considers that his examination has not been properly carried out, or that the grade in which he is placed is not correct. His appeal will come before the appeal tribunals throughout the country. In future the appeal tribunals will have attached to them medical assessors selected and appointed by the Local Government Board in England and Wales and by the Scottish Office in Scotland. Re-examination of the men on appeal will be undertaken by these medical assessors if the appeal tribunal considers, on hearing the case, that further examination is desirable. The decision of these medical assessors will be considered as final, inasmuch as it is the considered statement of the man's physical condition and the grade in which he should be placed.

Thus, as Sir Auckland Geddes pointed out, a new principle is introduced. The Ministry of National Service will only be responsible for providing the machinery for the ordinary medical examination. Any appeal in connexion with medical examination will rest with medical men neither appointed nor controlled by the Ministry, but with medical practitioners appointed by the Local Government Board or the Scottish Office, as the case may be. Drawing to the close of his admirably lucid statement, Sir Auckland Geddes made a remark which deserves emphasis: A long-drawn war between nations wholly mobilized (he said) could only be won by living healthily and by employing healthy armies—healthy in body, and with a healthy public opinion in them and behind them, to fight on and on until the enemy nation collapsed.

The plan appears to have been ably constructed, and shows a proper appreciation of the medical position and of the part which medical examining boards should play in the selection of recruits. If it works as well as may be expected from the information so far published, it ought to remove all legitimate causes of grievance.

AMERICAN MEDICAL OFFICERS IN ENGLAND.

DURING the past week or so the medical profession and the public have become aware through the newspapers that many civilian medical practitioners working at military hospitals have been officially informed that their services will no longer be required, as their duties are to be taken over by medical officers from the United States. It appears that notifications to this effect have been issued in most, if not all, the home commands. The decision seems to have been communicated, in some cases at least, in a very curt manner, and not to have been accompanied by any acknowledgement of the services rendered. The matter first came to the notice of the Central Medical War Committee on September 11th, when it was informed by a Local Medical War Committee that ten medical practitioners attached to a local military hospital had been warned that they might be replaced almost at once by whole-time American surgeons. The Committee thereupon addressed a letter to the War Office inquiring whether such changes were in contemplation on a large scale throughout the country, and, if so, whether the American surgeons would be permanently posted for duty or would be liable to be recalled for service with the United States army. The reply of the Army Medical Department stated that the "arrival of a contingent of medical officers of the United States army has made it

possible to release a number of medical practitioners who are now engaged on part-time duty in hospitals, and who will thus become available to meet the needs of the civil population. The question of the withdrawal of American officers from service with the British Forces has been raised with the American authorities, and will form the basis of a further communication to you later. It is hoped, however, that the permanent retention of a certain number will be possible." The Executive Committee of the Central Medical War Committee then inquired whether the substitution had been applied in cases where it had not been ascertained that there was any special need for additional attendance on the civil population, and added that the Local Medical War Committee in one important area had stated that the recent action, particularly as it had been taken without discussion with the Central Medical War Committee, and consequent discrimination between the areas in which such a step is necessary and those in which it is not, imperils the co-operation with the local military authorities, which in the past has proved eminently successful. There has of course been no suggestion from any quarter that the help of American colleagues would not be welcomed in this country. Criticism has been directed against the manner in which the policy has been put into operation and the lack of consideration shown for the medical men displaced at short notice. From inquiries we have made, we understand that the proposal to utilize the services of American surgeons in home commands at short notice was due to the Army Medical Department, through some error in the cables, only receiving intimation that 135 American medical officers were coming to this country when they had already arrived and were on their way to London. The United States medical authorities expressed the wish that these American officers should be posted as soon as possible. Steps were then taken to ascertain from the home commands how many part-time civil medical practitioners could be released, and it was suggested that one American surgeon might often be able to replace two part-time civil practitioners. The American surgeons were accordingly posted to the various commands and we have reason to believe that some misapprehensions arose as to the best manner of their disposal. It is not the intention of the War Office that medical officers performing important work in hospitals should be relieved, and a letter of instruction has been sent out to the commands that if and when it should be considered possible to replace part-time men in hospitals engaged in surgical work, this shall only be done gradually after consultation between the commanding officer of the hospital and the consulting surgeon of command, and only when the latter is of opinion that the American surgeons have received such training in war surgery under a surgical specialist as will fit them for independent charge of military wards. We understand also that a letter of thanks will be addressed to any part-time officers now released, and that in it a hope will be expressed that they will again place their services at the disposal of the War Office should necessity arise. We fear that the incident has produced a very unfortunate impression, and that the hurried action taken has caused much soreness. The War Office no doubt finds justification for the immediate employment of American medical officers in the notification addressed to it by the Central Medical War Committee on August 3rd, in which it was stated "that no more medical men can be called upon to take commissions in the R.A.M.C. without seriously endangering the supply of doctors for the treatment of the civil community." But we think it unfortunate that before actually replacing part-time medical officers attached to hospitals by American medical officers, the War Office did not consult the Professional Committees as to the places where this could be done with the greatest advantage to the civil community and the R.A.M.C. As we have on many previous occasions observed, we believe

that friction would be avoided and the work of the military authorities facilitated if there were closer co-operation between the military medical authorities and the representative bodies of the civil profession.

RECENT RESEARCHES ON TUBERCULOSIS.

UNDER the aegis of the Henry Phipps Institute at Philadelphia a series of experimental researches have been carried out during the last few years. Some of them have already appeared in American scientific periodicals, but have now been published collectively in the Thirteenth Annual Report of the Institute.¹ They cover a wide field, but all have a direct bearing upon the study, treatment, or prevention of tuberculosis. An interesting inquiry into the dietary of the ordinary dispensary patient and the actual food values of the articles consumed daily by the various types has elicited proof that in the great majority of cases the diet did not come up to the accepted standard of calories by one-fifth. The explanation given is twofold. Poverty, on the one hand, may account for a good deal, but ignorance on the part of the housewife is responsible for the greater part. A close investigation as to the purchasing power of 10 cents, as expended by different classes, such as Italians, Russians, negroes, and Jews, showed a marked difference in results. The prevention rather than the treatment of disease, and especially of tuberculosis in connexion with childbirth, is the subject of an interesting account of work carried on at the institute and the Babies Hospital. Prenatal work among the well-to-do, as well as among the poorer classes, is effecting many changes for the better, but the mortality from preventable causes is still appallingly high. A very important, though short, communication on the subject of latent syphilitic infection of the lungs deserves special note. Pulmonary lesions unaccompanied by fever or sputum are almost always attributed to quiescent tubercle, but in many instances the Wassermann test has revealed the specific taint and special treatment has healed the lesion. Salvarsan has proved as effective in such cases as in cutaneous affections due to the same cause. Attempts to destroy or annul the activity of the tubercle bacillus in the tissues have occupied the minds of experimental pathologists in many lands since the selective action of tuberculin was first demonstrated. It has now been found that certain substances, of which trypan-red is thought to be the best, have a definite effect upon the blood vessels surrounding a tuberculous lesion, and that in the laboratory such substances will inhibit the growth of the bacilli when used in sufficient concentration. Details are given of the results so far obtained, and they undoubtedly form a substantial foundation for future work. Many other papers of interest bearing upon difficult chemical questions, and notably as to the presence of iodine in tuberculous and other organic tissues, will be found in the report.

JOHN HUNTER'S SURGICAL INSTRUMENTS.

THE Council of the Royal College of Surgeons of England has just issued a descriptive catalogue of certain Hunterian relics contained in the museum of the College. The preparation of this catalogue was undertaken by Mr. Alban Doran, to whom it has evidently been a labour of love. The Hunterian collection did not originally include the series of surgical instruments which has been accumulated since the Government purchased Hunter's preparations in 1800, and committed them to the care of the Corporation, afterwards the College, of Surgeons. Among the additions to that series is the little group of interesting relics described and annotated by Mr. Doran. These instruments of bygone workmanship were John Hunter's property, and were employed by him in his surgical practice. They include a pair of sharp-pointed scissors and a spatula for

a surgeon's pocket case, the spatula fenestrated for greater lightness; a pair of old-fashioned X-shaped dressing forceps, which look very strange to modern eyes; two surgical needles "of well-tempered steel" in a wooden case covered with shark skin; a sturdy lithotomy scalpel, which is the only instrument in the whole series of relics which was admitted by John Hunter's contemporaries to be of his own design; William Hunter's uterine polypus loop, employed by his younger brother for passing ligatures in the treatment of aneurysm; an early type of flexible silver catheter; a charming tortoise-shell case of lancets; and, lastly, a pair of pocket scales in a solid wooden box hollowed out to receive them. In his compact notes Mr. Doran sets out the evidence showing that each relic belonged to John Hunter, and indicates the relations of each instrument to patterns in vogue among Hunter's contemporaries, based on careful search of old surgical books and plates. The catalogue is worthily illustrated, and forms one more tribute to the memory of the great master.

THE METROPOLITAN ASYLUMS BOARD.

IN common with nearly all such publications the annual reports of the Metropolitan Asylums Board now appear in a greatly attenuated form. Before the war they were substantial volumes of some 260 pages, bound in full cloth and decorated with charts. The reports for 1915 and 1916 are in comparison slender pamphlets of fifty pages or so, in paper covers. The report for 1916, which has just been issued, consists merely of a general review of the year's work, and of statistical tables. The number of war refugees under the Board's care was very greatly reduced during the year, the total number of admissions being little more than a fifth of the total for 1915. Since the beginning of the war three of the Board's hospitals, containing more than 4,400 beds in all, have been handed over to the Government for military purposes; part of the High Wood School has been set aside for the accommodation of soldiers; and soldiers suffering from tuberculosis and other diseases have been accommodated. Further, a number of patients from the London County Council's asylums have been received, with a view to enabling one of the large asylums to be handed over for military purposes, and a similar course has been adopted in the case of sane epileptics from the Belmont Institution. The Board has had great difficulty in maintaining its land ambulance service, which is, of course, one of the chief links in the chain of its activities. The shortage of drivers was largely made good by the employment of women, but the staff of skilled mechanics employed in repairing and overhauling the motor vehicles, and maintaining them in running order, was much depleted, and in spite of every effort the shortage persists. The result would have been serious were it not that during the year the prevalence of infectious diseases in London was unusually low, and this was exactly reflected in the lessened number of patients conveyed to hospitals and elsewhere by the Board's ambulances. The remarkably small number of scarlet fever cases was a great boon in many ways to the managers of the Board, enabling them to carry on with depleted staffs, and to accede to many requests from the military and naval authorities for the removal and treatment of soldiers and sailors with infectious diseases.

A MINISTRY OF HEALTH.

IN several newspapers this week there have appeared more or less detailed accounts of a scheme for the establishment of a Ministry of Health, which is said to have been approved and adopted by the Standing Joint Committee of Approved Societies, by the Emergency Committee of the National Association of Insurance Committees for England and Wales, and by the Faculty of Insurance. This scheme is put forward with a plain hint that the Government is expected to swallow it whole and take the necessary steps

¹ Thirteenth Report of the Henry Phipps Institute for the Study, Treatment, and Prevention of Tuberculosis. University of Philadelphia, 1917.

to put it into action without delay. According to one account, the Government is called upon to take in hand the requisite legislative and administrative measures at the beginning of the autumn session, so that the new Ministry may be set up and become a going concern by Christmas. The scheme is comprehensive enough, and the only wonder is that those who put it forward should have been able to reach unanimous decisions embracing such a variety of principles and details. Broadly stated, the proposal is that the new Ministry should begin as a combination of certain public health functions of the Local Government Board, the functions, both medical and financial, of the National Insurance Commission for England and Wales, the maternity and infant welfare functions of the Board of Education (whatever that means), the midwifery functions of the Privy Council office, and certain new functions in respect of the care and supervision of the blind. To these duties are to be added, as soon as may be, certain other public health functions of the Local Government Board, the work of the Registrar-General's office, the factory inspection functions of the Home Office, and the appointment of certifying surgeons under the Factory Acts, together with the functions of the Board of Control. Other functions to be added at a later date are the remaining public health activities of the Local Government Board, notably housing, the supervision of the medical side of the Poor Law, and the supervision of the treatment of discharged and disabled sailors and soldiers. The powers and duties of the National Insurance Commissioners are to be transferred to the Ministry of Health, the Commissioners becoming, with their staff, officials of the new Ministry. Upon this point, however, two specific provisos are made which make the position of the authors of this scheme fairly clear: "In the exercise of the functions so transferred to the Minister, he (and, of course, his department) shall constantly have advice and guidance from a special body, to be appointed for the purpose by Order in Council, comprising persons having practical experience of National Health Insurance work. . . . Secondly, the bill should provide that the judicial and quasi-judicial powers and duties of the Insurance Commissioners shall not be transferred to the Minister, but shall be vested in, and exercised by, a special body, to be appointed for the purpose by an Order in Council, whose decisions on these matters shall be final." The outlined scheme provides for a special administrative office for Wales which could be developed later into a Welsh department of the Ministry; but it is suggested that Scotland and Ireland might prefer to work out their own arrangements in their own way, and set up each its own Ministry of Health. Lastly, we note that in order to make their plan achieve its purpose, the authors in a vigorous peroration demand "that unwilling authorities, obstructive interests and reactionary influences, shall be effectively dealt with"—a sentiment which all reformers will cordially endorse, though they may not agree as to which authorities, interests, and influences merit these epithets.

THE ALCOHOLIC FACTOR IN INSANITY.

DR. H. M. POLLOCK, statistician to the New York State Hospital Commission, has published a paper¹ on the decline of alcoholism as a cause of insanity, based upon an inquiry into the history of the 58,000 patients admitted during the past eight years into the thirteen civil State hospitals of New York State. During this period the habits of every patient were inquired into on admission, and a statistical data card was prepared for each case and forwarded to the Bureau of Statistics. Dr. Pollock summarizes the results of this investigation in tabular form. The first table shows the number and proportion of cases of alcoholic insanity among patients admitted during each year. In 1909 the percentage of alcoholic cases among

all admissions was 10.1; in 1910 9.8; in 1911 9.7; in 1912 9.4; in 1913 9.0; in 1914 7.0; and in 1915 5.4; in 1916 the percentage rose to 5.7. Since the trend of these figures might be interpreted as being due to changes in classification rather than to changes in the use or influence of alcohol, a further table is given showing the number and percentage of cases for each year in which the intemperate use of alcohol was recorded on first admission. This also shows a general decline, as does a third table giving the yearly rates of new cases of alcoholic insanity admitted to the civil State hospitals per 100,000 of general population of the State. The conclusion drawn from these figures is that the alcoholic cases annually admitted to the State hospitals in question since 1909 have decreased both relatively and absolutely, and that intemperance as a contributing factor in causing mental disease has gradually diminished. These results are attributed by Dr. Pollock to improvement in the habits of the general population with respect to the use of alcohol. But in appraising them we may well bear in mind the word of caution sounded by Dr. Maurice Craig in his discussion of alcoholism as a cause of insanity.² "No doubt it is a very potent cause, but it may also be an early symptom of mental disease. The physician must be careful to distinguish between cause and effect. Further, defective control may be the scar left by a former attack of insanity, and it may show itself in a tendency to drink."

MEDICINE IN KOREA.

FROM a summary of the annual report on reforms and progress issued by the Korean Government in July, 1916, which appears in the review of current periodicals by the staff of the Research Department of the Severance Union Medical College, Seoul (vol. ii, part 2), we learn that in the year 1914-15 for the medical care of a population of more than thirteen millions there were one Government general hospital and 18 provincial charity hospitals, and 145 public and private hospitals, including missionary institutions. The number of fully qualified doctors was 641, besides 91 whose licence was limited; 20 dentists; and 323 qualified midwives, and 74 whose practice was limited. In addition to these there were 5,827 Korean practitioners of the old school. The Government medical school at Seoul had 42 teachers and 160 students. Degrees were conferred on 24 students during the year. The staffs of the Government hospital and the 18 charity hospitals numbered 104 physicians, 45 pharmacists, and 358 nurses. The number of cases treated during the year 1914-15 was 443,868. Notification of cholera, typhoid, paratyphoid, dysentery, diphtheria, typhus, scarlet fever, and small-pox is compulsory. Small-pox fell from 2,536 cases with 481 deaths in 1910 to 140 cases with 12 deaths in 1914. The reduction is attributed to vaccination; during the year under review 1,794,438 vaccinations were reported.

By the addition of the party recently organized, the number of American orthopaedic surgeons now available for military orthopaedic work in this country is 87.

MAJOR J. DUNDAS GRANT, consulting surgeon to the Central London Nose, Throat, and Ear Hospital, has been appointed Chairman of the Special Aural Board which has been set up by the Pensions Minister for the purpose of dealing with the cases of deaf discharged soldiers.

SIR ARTHUR WHITELEGGE, K.C.B., for more than twenty years the chief inspector of factories and workshops at the Home Office, is about to retire on reaching the age limit. An arrangement has been made under which Sir Arthur Whitelegge will continue to give his services to the factory department in an advisory capacity on questions of a technical and scientific character.

¹ *Psychiatric Bulletin of the New York State Hospitals*, vol. ii, No. 2, 1917.

THE WAR.

NATIONAL EXPERIMENTAL LABORATORY FOR ARTIFICIAL LIMBS.

THE Minister of Pensions on September 17th received a private deputation from the committee of the Queen Mary's Convalescent Auxiliary Hospital, Roehampton, for soldiers and sailors who have lost their limbs in the war, with regard to the proposal to establish a national experimental laboratory for controlling the design and manufacture of artificial limbs for disabled soldiers. According to the published accounts, the deputation expressed the hope that far better types of limbs than are now being supplied would gradually be evolved if experiments were carried on and the experience of patients was made full use of. Mr. Hodge, in reply, stated that immediate steps would be taken to raise the funds for the establishment of such a laboratory, which might eventually develop into a national factory for manufacturing artificial limbs. For the present, however, he expressed himself as opposed to the establishment of such a national factory. He considered that the managing committee of the national experimental laboratory should be a small body representative of surgeons and mechanical experts, and should be distinct from any committee of management of special hospitals. It would be directly responsible to the Ministry of Pensions, and would be equipped with sufficient powers to make sure that the improvements recommended should be applied to the manufacture of artificial limbs.

HONOURS.

THE name of Captain Noel Godfrey Chavasse, R.A.M.C., heads the list of honours announced in the *London Gazette* of September 14th, as having won the great distinction of a bar to the Victoria Cross. This gallant officer had previously received the Military Cross on January 19th, 1916, and the Victoria Cross on October 26th, 1916. He has unfortunately since succumbed to his wounds, as recorded in our issue of August 18th, 1917. He was one of the four sons of the Bishop of Liverpool, all of whom have served with distinction in the army during the war. The heroic acts for which the bar is awarded are thus described:

Bar to V.C.

Captain Noel Godfrey Chavasse, V.C., M.C., R.A.M.C., attached Liverpool Regiment.

Though severely wounded early in the action whilst carrying a wounded soldier, Captain Chavasse refused to leave his post, and for two days not only continued to perform his duties, but in addition went out repeatedly under heavy fire to search for and attend to the wounded. During these searches, although practically without food during this period, worn with fatigue, and faint with his wound, he assisted to carry in a number of badly wounded men over heavy and difficult ground. By his extraordinary energy and inspiring example he was instrumental in rescuing many wounded who would otherwise have undoubtedly succumbed. This devoted and gallant officer subsequently died of his wounds.

Special supplements to the *London Gazette* issued on September 17th contain lists of awards for distinguished services in the field. The lists include the following medical officers:

To be Companions of the Distinguished Service Order.

Temporary Captain Lewis Anderson, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty. He carried out his duties for forty-eight hours without relief, attending to over 100 cases and working under the most adverse conditions. He was exposed throughout to intense and heavy fire of shell and gas shells, which rendered it necessary for him to work in a mask. The following night, after his battalion had been withdrawn, he returned to search for wounded in the front line, which was still in close contact with the enemy, and, after working for several hours under heavy shell fire, he collected and evacuated all his wounded, having displayed magnificent devotion and the utmost contempt for danger throughout.

Major Robert Archer Lloyd, M.D., I.M.S.

Lieutenant (Temporary Captain) Arthur Frederick Isbell Patterson, R.A.M.C.

Captain (Temporary Lieut.-Colonel) Norman Cecil Rutherford, M.B., F.R.C.S., R.A.M.C.

For conspicuous gallantry and devotion to duty when in charge of an advanced dressing station. He worked continuously under heavy shell fire, evacuating the wounded from the forward area, and it was owing to his splendid example of devotion that the work was efficiently carried out.

Military Cross.

Captain John Ernest Affleck, C.A.M.C.

For conspicuous gallantry and devotion to duty. He crawled along a shallow and much exposed trench to rescue a very severely wounded officer, whose life depended upon an immediate operation.

With the assistance of a stretcher-bearer he managed to get the wounded man out on a blanket to a place where he could be evacuated. The task was a very slow and dangerous one, by reason of their being completely exposed to enemy snipers, but Captain Affleck did not hesitate to risk his life in order to do all that was humanly possible for this wounded officer.

Captain John Arthur Bell, R.A.M.C.

For conspicuous gallantry and devotion to duty during a heavy bombardment. He proceeded along a road which was exposed to the most intense shell fire in order to attend to four wounded officers. He dressed their wounds and remained with them until they were evacuated by motor ambulance, which was only accomplished with the greatest difficulty owing to the heavy shelling. His absolute disregard of danger and devotion to duty amidst terrific shell fire were exceptionally splendid and beyond all praise.

Captain John Bernard Cavanagh, M.B., R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty when in charge of bearers. He exposed himself to shell fire for forty-eight hours with splendid fearlessness, keeping all the time in touch with aid posts in the captured line, thereby ensuring a rapid evacuation of the wounded.

Captain Clarence Hamul Denyer, R.A.M.C.

For conspicuous gallantry and devotion to duty when in command of divisional bearers. It was due to his fearless and capable handling of his party that the evacuation of the wounded was carried out with rapidity and success.

Temporary Captain Charles Dundee, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty. He worked for three days, bandaging the wounded under fire, and successfully evacuating every case in his battalion almost as soon as it occurred. Over five hundred cases passed through his hands, and he displayed a splendid spirit of energy and devotion.

Temporary Lieutenant David Hammond Fraser, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty. Whilst his battery was under very heavy gas bombardment a shell wrecked the officers' mess dug-out and buried two officers and five men. Lieutenant Fraser, helped by a corporal, most gallantly assisted to rescue the buried men and restore respiration, entering the dug-out several times, until he eventually collapsed from the gas. On recovering consciousness he again attempted to enter the dug-out, but was prevented from doing so. Later, he collapsed again and remained unconscious for a long time. It was due to his promptness and energy that no more than two of the gassed men succumbed.

Temporary Captain Augustus Joseph Hickey, R.A.M.C.

For conspicuous gallantry and devotion to duty when in command of an advanced dressing station. He worked with the utmost energy and disregard of danger for forty-eight hours under shell fire, during which time he passed through more than 700 wounded. His skill and devotion saved many lives.

Temporary Captain William Bird Loveless, R.A.M.C.

For conspicuous gallantry and devotion to duty in tending the wounded under heavy shell fire. Although wounded in the face early in the day, he did not leave his post, but continued with his work until he came out of action with his battalion, displaying splendid keenness and devotion to duty.

Temporary Captain Anthony John McCreadie, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty under heavy shell fire and in most trying circumstances. He worked alone and incessantly for thirty-six hours in the open attending to the wounded, and on two occasions he carried men under cover and dressed them. He evacuated all the wounded with admirable rapidity and efficiency, and his coolness and disregard for personal safety under fire afforded a magnificent example to all ranks. He has displayed similar gallantry on other occasions.

Captain John Morrison Milne, R.A.M.C.

For conspicuous gallantry and devotion to duty. When a dug-out containing combustion products was blown in and the inmates buried he procured oxygen cylinders and played them into the dug-out, thereby saving their lives. He also assisted most untiringly in digging out the men, who owe their lives to his promptness and gallantry under heavy shell fire.

Temporary Captain Samuel Ernest Picken, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in going forward under heavy shell fire and attending to the wounded in advanced trenches and shell holes. He remained in the shelled area for a long period, working incessantly and efficiently at the dressing and evacuation of the wounded. He has always shown the same gallant spirit and devotion to duty.

Captain James Calvert Spence, M.B., R.A.M.C. (S.R.).

For conspicuous gallantry and devotion to duty in proceeding to a battery that was suffering heavily from intense enemy shell fire, and continuing to search blown-in dug-outs and tend the wounded under heavy fire. He displayed exceptional coolness and gallantry on this occasion, and on many previous occasions he has carried out his duties with magnificent devotion.

Temporary Captain Hugh Frederic Wickens, M.B., R.A.M.C.

For conspicuous gallantry and devotion to duty in attending to the wounded whilst the camp was being heavily shelled. The dressing station was totally unprotected, and when it was eventually destroyed by enemy shell fire he showed splendid initiative and coolness in re-establishing his station elsewhere, continuing to clear the wounded and do his work in the most gallant and devoted manner. He has on several previous occasions displayed conduct of the same high order.

To be Brevet Lieut.-Colonel.

Major (temporary Lieut.-Colonel) R. M. Carter, F.R.C.S., I.M.S. (with effect from April 26th, 1916, inclusive).

Sergeant-Major L. J. Richardson, R.A.M.C., has been awarded the Military Cross. One acting lance-corporal of the R.A.M.C. receives the D.C.M.; one sergeant of the R.A.M.C. is awarded a bar to the Military Medal; eight non-commissioned officers and twenty-three privates of the R.A.M.C., two non-commissioned officers and one private of the A.A.M.C., and two

nursing sisters, and one staff nurse of the Queen Alexandra Imperial Military Nursing Service Reserve, receive the Military Medal, and four privates of the R.A.M.C. receive the Meritorious Service Medal.

OFFICERS COMMENDED.

The names of the following medical officers have been brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the war:

Surgeon-Generals: W. G. Birrell, J. D. Edge, C.B., W. L. Gubbins, K.C.B., M.V.O.; O. E. P. Lloyd, V.C., C.B. (ret. pay); W. F. Stevenson, C.B.

Honorary Surgeon-General W. R. Smith.

Colonels: G. G. Adams, L. J. Blandford, W. H. Bull, P. C. Burgess, E. Butt, R. Caldwell, Sir J. R. A. Clark, B. B. Connolly, C.B. (ret. pay), A. E. J. Croly, J. H. Daly, J. R. Dodd (ret. pay), H. H. Forman, J. Griffiths, R. I. D. Hackett, S. S. Hoyland, R. Jennings, T. J. R. Lucas, C.B. (ret. pay), W. A. May, C.B., C. H. Melville, L. T. M. Nash, F. P. Nichol, C. P. Oliver, W. J. R. Rainsford (ret. pay), A. F. Russell (ret. pay), H. M. Sloggett, O. Todd, C. A. Webb.

Brevet Colonel E. M. Pilcher.

Temporary Colonel F. Kelly.

Surgeon-Colonel A. Thorne.

Honorary Surgeon-Colonels: W. C. James, W. M. Roocroft.

Lieut.-Colonels: F. H. Appleby, Sir James Barr, F. W. Begbie, J. R. Benson, H. Bramwell, G. A. T. Bray, H. A. Bray, C.M.G., J. F. Brodie, H. E. Bruce-Porter, G. H. Bull, I.M.S. (ret. pay), E. M. Callender, W. P. Carson, I.M.S., C. W. Cathcart, J. Chaytor-White, I.M.S., T. H. M. Clarke, T. H. F. Clarkson, G. J. Coates, W. Coates, C.B., M. A. T. Collie, I.M.S., M. P. Corkery, R. Cottell, Sir W. R. Crook-Lawless, R. O. Cusack (ret. pay), V. G. Drake-Brockman, I.M.S., W. C. Edwards, F. W. Ellis, N. Faichnie, Sir J. Fayrer, G. M. Goldsmith, R. H. Hall, T. W. O. H. Hamilton, L. W. Harrison, M. L. Hearn (ret. pay), F. S. Irvine, C. James, J. B. Jameson, I.M.S., P. H. Johnston, A. A. Lyle (ret. pay), A. W. MacKintosh, J. R. Mallins, J. Mill, L. A. Mitchell, J. M. Moir, A. H. Morris, R. E. R. Morse, C. W. Mansell Moullin, Sir S. F. Murphy, H. K. Palmer, Sir A. Pearce Gould, E. V. A. Phipps, D'A. Power, M.B., W. L. Reade, E. S. Reynolds, B. Riddell, C. F. Routh, W. Rowney (ret. pay), J. V. Salvage, P. C. Smith, W. F. Somerville, M. Swaby, H. Thomson, I.M.S., S. J. Thomson, I.M.S., E. N. Thornton, S.A.M.C., J. Tidbury, T. B. A. Tuckey (ret. pay), C. H. W. Whitestone, S. R. Wills, A. R. Wilson, G. H. Younge (ret. pay).

Surgeon Lieut.-Colonel P. H. Whiston.

Temporary Lieut.-Colonels: G. A. Bannatyne, D. Buncombe, J. B. Byles, A. Carless, A. H. Carter, H. G. Cook, A. P. Dodds-Parker, T. H. Gibbon, E. Goodall, J. Keay, H. A. Kidd, J. R. Lord, S. Mort, Sir B. G. A. Moynihan, C.B., W. T. Prout, F. Romer, A. Simpson, W. Taylor, D. G. Thomson, W. J. N. Vincent, T. B. Winter, J. F. Woodyatt, W. Wrangham, G. A. Wright.

Honorary Temporary Lieut.-Colonel H. Chaffer.

Majors: J. A. Anderson, R. Y. Anderson, W. E. A. Armstrong, I.M.S., R. A. Bickersteth, C. Bramhall, H. A. Bransbury, A. J. Chambers (ret. pay), H. A. Cummins, E. N. Cunliffe, A. C. Farquharson, E. G. French, A. M. Gossage, D. J. Graham, E. Gray, T. W. Griffith, G. P. D. Hawker, R. W. W. Henry, W. A. L. Holland, C. H. Hopkins, J. K. Jamieson, W. Kirkpatrick, J. P. Lynch, W. McConaghey (attached to the Egyptian army), W. G. Macfee, J. N. Macmullan, A. A. W. Merrick, F. W. Mott, A. Mowat, R. C. Rodgers, G. B. Russell, M. S. Skirving, A.A.M.C., C. G. Spencer (ret. pay), G. H. Spencer, H. K. Steele (S.R.), W. S. V. Stock, J. Tait, H. W. M. Tims, W. E. F. Tinley, C. W. Vining, D. Walker, S. G. Webb, W. E. Wynter, A. G. Yates.

Temporary Majors: T. S. Allan, H. W. Bruce, W. R. Dawson, C. B. Dobell, J. H. Hall-Edwards, L. C. V. Hardwicke, D. W. Hume, A. M. Humphrey, J. S. Law, J. R. Lee, D. K. MacDowell, C. V. MacKay, H. G. Magrath, H. C. Marr, J. S. Morrow, E. H. T. Nash, A. Neve, C. Noon, L. Owen, F. C. Purser, T. B. Rhodes, R. G. Riches, N. Roberts, F. M. Rodgers, R. G. Rows, W. Scatterty, G. T. S. Sichel, G. Simpson, H. J. Stiles, J. G. Taylor, F. S. Toogood, J. C. Woods, R. Worth, C. S. Young.

Surgeon-Majors: J. F. G. Dill, F. F. MacCabe (S.R.).

Temporary Honorary Major W. I. de C. Wheeler.

Captains: T. Armour, W. G. Ball, A. S. Barnes, E. C. Bradford, E. A. P. Brock, F. G. Cayley, E. M. Corner, L. Courtauld, C. S. Dean, G. H. Domy, J. S. C. Douglas, G. L. Findlay, N. S. Finzi, W. Gibbs-Lloyd, E. E. Glynn, G. W. Goodhart, A. H. Gosse, F. S. Hawks, T. J. Horder, F. H. Humphries, A. A. Jubb, W. E. Marshall, M.C., M.B., W. Martin, H. L. Munro, C. F. Petley, H. Pinto-Leite, C. F. Read, C. H. Rook (S.R.), H. A. Scholberg, H. R. Sedgwick, S. G. Vintner, F. J. Wethered, J. A. L. Wilson (S.R.).

Temporary Captains: J. Bowes, C. W. J. Brasher, R. H. Brenridge, F. W. Broderick, R. Buchanan, J. Burnford, W. K. Carew, J. E. Carruthers, E. Chambers, A. Compton, W. B. Cosens, S. E. Denver, J. R. Dickson, E. D. Dobson, J. D. Duncan, N. M. Falkiner, W. Fell, W. T. Finlayson, A. A. Forty, A. Griffiths, W. Griffiths, J. P. Helliwell, S. L. Hinde, A. C. Holden, A. L. Jackson, W. W. Jameson, I. Jones, A. M. Kennedy, A. B. Laidlaw, H. C. T. Langdon, A. Landie, P. W. MacLagan, J. M. MacMillan, J. T. McCullagh, L. W. Mortimer, G. Muir, C. E. Murphy, N. H. Oliver, J. F. O'Malley, R. E. F. M. Pearce, J. H. Peek, A. Phillips, J. R. H. Ross, C. Samut, W. Sansom, W. S. Sprent, W. S. Stalker, L. H. Y. Stephen, C. R. Stewart, A. Stodart-Walker, F. W. S. Stone, R. W. Sutherland, B. Sweeten, R. R. Wallace, G. C. W. Williams, E. W. Witham.

Lieutenant T. Croft.

Temporary Lieutenant A. C. Pickett.

Quartermasters and honorary Majors: J. H. W. Beach, T. F. Brake (ret. pay), J. Gillman, H. Johnson, H. Lockhart, H. Woolley.

Quartermasters and honorary Captains: F. Bruce (ret. pay), R. Hawkey (ret. pay), J. Mathews, A. J. Pilgrim, J. C. B. Whitehorn.

Quartermasters and honorary Lieutenants: T. Gibbs, C. Hayward, E. Janes, L. Matthews, H. H. Ross, S. Sully, A. G. Tod, F. B. Wild.

Temporary Quartermasters and honorary Lieutenants: T. Allen, A. E. Hanrahan, C. R. W. Keefe, J. Ogden, J. Tonkinson, L. W. Whittaker, J. H. Withy.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Wounded.

Surgeon Probationer H. J. Phillips, R.N.V.R.

ARMY.

Died of Wounds.

CAPTAIN B. WOODHOUSE, R.A.M.C.

Captain Bernard Woodhouse, R.A.M.C., died of shrapnel wounds on September 5th, aged 28. He was the younger son of the late Lister Woodhouse, of 3, Berkeley Place, Wimbledon, and was educated at University College, London, taking the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1913. He entered the R.A.M.C. as lieutenant on July 25th, 1913, and was promoted to captain on March 30th, 1915. He was attached to the Welsh Regiment when killed.

D. J. P. PRITCHARD.

Dom John Placid Pritchard, of Erdington Abbey, died on September 4th, aged 22, of wounds received on September 1st at Sultanabad, in Persia, while serving as captain in the Russian medical service. He was the son of W. B. Pritchard, of Glenwood, Eltham Road, Lee, and was a member of the Order of St. Benedict.

Wounded.

Lieut.-Colonel J. Barkley, R.A.M.C. (T.F.).

Captain A. L. Anthony, R.A.M.C. (S.R.).

Captain P. A. Doyle, R.A.M.C. (temporary).

Captain A. H. Falkner, R.A.M.C. (T.F.).

Captain N. J. H. Garvin, M.C., R.A.M.C. (temporary).

Captain H. G. Janion, M.C., R.A.M.C. (temporary).

Captain R. W. Hodson Jones, R.A.M.C. (temporary).

Captain W. C. D. Maile, R.A.M.C. (temporary).

Captain L. J. Moir, R.A.M.C. (temporary).

Captain J. C. Sale, M.C., R.A.M.C. (temporary).

Captain L. R. Shore, M.C., R.A.M.C. (temporary).

Captain G. W. Stanley, R.A.M.C. (temporary).

Captain J. S. Taylor, R.A.M.C. (temporary).

Captain L. M. Weeks, R.A.M.C. (temporary).

Captain T. H. Whittington, R.A.M.C. (temporary).

Captain W. L. R. Wood, M.C., R.A.M.C. (T.F.).

Lieutenant M. J. McAuley, R.A.M.C. (temporary).

Lieutenant W. G. McConnell, R.A.M.C. (temporary).

Lieutenant H. Snape, R.A.M.C. (temporary).

Captain Janion's name has twice recently appeared as wounded in the casualty lists—in that of August 30th, and again in that of September 12th.

DEATHS AMONG SONS OF MEDICAL MEN.

Beckingsale, John Edgar, Second Lieutenant Duke of Cornwall's Light Infantry, only son of Dr. D. L. Beckingsale, at present of Towyn, Merioneth, Wales, killed on August 22nd, whilst leading his platoon into action, aged 30. He was recently living in Southern California.

Eminson, Herbert Luther, Lieutenant 8th Battalion South African Infantry, second son of Dr. and Mrs. Eminson, of Bootle, Liverpool, killed in action in East Africa on July 19th, aged 37 years. He was educated at the Collegiate School, Elsworth, and Atherstone Grammar School. After leaving school he studied mining engineering. He took part in the Boer war, with the Staffordshire Imperial Yeomanry; and at the termination of the war settled down in South Africa, being appointed one of the surveyors of roads for the works department of the Government of Natal. When the present war started, he was engaged in road surveying in Zululand; he gave up the work at once and joined up as a private for duty in the Union of South Africa, or for operations against the German forces in British and German East Africa.

Hill, H. F., M.C., Captain 18th Battalion Middlesex Regiment, died September 5th of wounds received while engaged in superintending trench digging operations. He was the elder son of

Captain A. A. Hill, R.A.M.C., of Wolstanton, Stoke-on-Trent. Captain H. F. Hill was educated at the High School, Newcastle-under-Lyme, and was a scholar of Clare College, Cambridge. He was about to proceed to that university when he responded to the call. He was not 19 when gazetted captain, and besides winning the M.C. had been mentioned in dispatches for excellent work as a pioneer officer.

Rinnell, Thomas Squier, Second Lieutenant Suffolk Regiment, eldest son of Dr. J. S. Hinnell of Bury St. Edmunds, reported missing on August 12th, 1915, now presumed killed on that date, aged 21. His first commission was dated October 31st, 1914.

Humphreys, J. Alan, Second Lieutenant Royal Field Artillery, youngest son of Lieut.-Colonel C. Humphreys, R.A.M.C. (T.F.), county medical officer for Montgomery, killed recently, aged 19. He was educated at Llandoverly College, enlisted a year ago as a gunner in the artillery, and subsequently obtained a commission in the Special Reserve, R.F.A. He went to the front last June.

Jacob, Donald M., Private, Canadian Forces, youngest son of the late Dr. Archibald H. Jacob, of Dublin, killed August 21st.

Lawrenson, Raymond F., Lieutenant Cheshire Regiment, only son of Dr. Harman F. Lawrenson, died September 5th of wounds received August 16th, aged 28.

Procter, George Henry Vincent, Second Lieutenant Lancashire Fusiliers, eldest son of the late Dr. Herbert Procter, of Southborough, Kent, killed September 6th, aged 21.

Ratton, Joseph Holroyd, Major Royal Garrison Artillery, eldest son of Lieut.-Colonel Ratton, I.M.S. (retired), of Blackheath, killed September 2nd, aged 35. He was educated at Stonyhurst College, and entered the artillery from Woolwich in 1901, was promoted to captain on July 23rd, 1914, and to major in July, 1916. On September 1st, 1911, he was seconded for service with the Gold Coast Regiment, in which he was intelligence officer. During his service in Africa he explored the hinterland of the Gold Coast and of the French Ivory Coast, mapped out a hitherto unsurveyed part of the country between the Gold Coast and the source of the Niger, served in the Togoland campaign, held the post of Acting Military Governor at Lorne, commanded a battery in the Cameroons campaign, and took part in the capture of Jaunde. He had since proceeded to another front.

Semple, H. S., M.C., Major Royal Engineers, eldest son of Dr. H. F. Semple of Budleigh Salterton, killed September 5th, aged 24. He became lieutenant on January 23rd, 1914.

Story, George Ernest, Lieutenant Royal Engineers, son of the late Dr. John Story of London, W., died at 3rd London General Hospital, Wandsworth, September 9th, aged 57.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

England and Wales.

THE SUPERSESSION OF THE MILITARY HOSPITAL STAFFS IN MANCHESTER AND SALFORD.

THE summary dismissal of the civilian part-time medical officers of the military hospitals in Manchester and Salford has caused a feeling of intense resentment against the War Office officials who may have been responsible, and this feeling is shared by the Local Medical War Committees, who received no intimation of the proceeding until the new arrangements were practically carried out. The medical officers themselves were generally under the impression that a month's notice would be given when their services were no longer required, but in practically every case only a curt notice was received that at the end of a week they would be "released," and the Local Medical War Committees received from the officer commanding 2nd Western General Hospital at Whitworth Street a note to the effect that owing to United States medical officers having been allocated to this unit, it was possible for a certain number of civil medical practitioners to be released in order to meet the needs of the civil population. In some of the hospitals the Americans have already commenced their duties, and it is only right to say that no blame can be attached to them for thus ousting the English doctors, as they have simply obeyed orders with which at least some of them are not well pleased.

Apart from the injustice thus inflicted on the English civilian doctors, the action of the military authorities is felt to be a distinct slight on the Local Medical War Committees, which, in the interests of all concerned, ought to have been consulted before such a step was taken. The committees have in the past done all that could be done to assist the military authorities. It was through the committees that the medical boards for the examination of recruits were formed, which relieved the authorities

from what they found to be a very difficult task. Moreover, as the committees by their constitution were in the best position to know what civilian doctors could undertake part-time work at military hospitals, the military authorities for some time past had consulted them before making appointments at the auxiliary hospitals. The committees, too, had faithfully carried out their duty of recommending what doctors of military age could be spared to join the forces; and, working as they did in close connexion with the Insurance Committees, they had been able to set free quite a large number of doctors for the army without unduly damaging the proper medical attendance on the civil population. This had been accomplished partly by arranging for the carrying on of the practices of the doctors who were thus set free to join the army. In the case of Salford the panel practitioners had voluntarily agreed to set aside several thousand pounds from the panel practitioners' fund, to be divided in fixed proportions among those panel practitioners who joined the army. In Manchester, too, an arrangement had been made which would provide as far as possible against loss through joining the army. In short, in every possible way the Local Medical War Committees, working with the Panel and Local Medical Committees and the Insurance Committees, had been the means of obtaining for the army the greatest possible number of medical men while at the same time guarding the needs of the civil population. All this purely voluntary work, which the army authorities could not have done, is now required in a way that cannot tend to encourage its continuance.

It has been stated that the appointment of the American doctors is intended to release a still further number of Manchester and Salford doctors to join the army or to attend to the needs of the civil population. This suggestion can only have been put forward by persons who do not fully understand the present conditions, for in the first place the dismissed doctors, with extremely few exceptions, are over military age, and in the second place, the needs of the civil population have already been sufficiently guarded by the Local Medical War Committees. The dismissed medical officers will now simply have to fill up their time with civil work, and any special experience which they may have gained at the hospitals in the treatment of the wounded will be lost to the army, and the wounded will have to depend on doctors who, however well qualified they may be generally, cannot claim the experience in the treatment of the wounded which the displaced medical officers have acquired. If there had been complaints against the displaced doctors, the matter would have borne a different aspect, but no complaints have been heard of. It may well be that the feeling of resentment will not result in any slackening in voluntary efforts to supply the needs of the army and the civil population, but the strongest protest is made against actions such as that in question, which inevitably tend to discourage that whole-hearted co-operation which is so desirable between the military authorities and civil bodies, both working for their country.

Correspondence.

RECURRENCE OF ADENOIDS AND TONSILS.

SIR,—In the JOURNAL of September 15th there is an admirable clinical lecture by Dr. Douglas Guthrie on "Some nose and throat diseases of childhood," but I cannot refrain from taking exception to his rather dogmatic statement in reference to the removal of tonsils and adenoids, that "after a thorough operation there is no such thing as a recurrence." I thought the same myself in earlier days, particularly as I observed that adenoid "recurrences" took place chiefly or entirely on the left side of the nasopharynx, the area most apt to escape the sweep of the surgeon's curette, and that the "regrowth" of tonsils was principally in cases in which the capsule of the gland had been left behind. But a wider experience has afforded me opportunities for watching cases in which I have sometimes on more than one occasion assured myself, both by sight and touch, of the complete clearance of the post-nasal space after operation, and yet I have later on noted the gradual regrowth of adenoid tissue

sufficient to call for a second operation. So, too, in regard to the tonsils. I can produce tonsils which have been enucleated intact in their capsules, and yet their original owners have suffered a regrowth of lymphoid tissue in the fauces, requiring further treatment. These cases have occurred in my own practice, and I have seen them as frequently from the hands of other operators, though some of them were amongst the most skilled in the land. I have at present under observation a boy in whom the adenoids have been twice removed by a leading London laryngologist. I removed them for the third time; at intervals, for nine months, I inspected the nasopharynx and found it smooth and clear. Recently I have observed the gradual regrowth of adenoid tissue in this boy's post-nasal space. It is well to add that he had measles in the spring, and that several of his relatives have required the adenoid operation more than once. The recurrence of tonsillar tissue I have watched whether the tonsils had been enucleated by the guillotine or by dissection.

Incomplete removal is, unfortunately, not uncommon; but true recurrence does take place in a very small proportion of cases. If we all recognized and explained to the public that a recurrence may possibly take place, even after the most thorough operation, parents would have less cause for complaint, and colleagues would be more charitable one to another.—I am, etc.,

London, W., Sept. 18th.

STCLAIR THOMSON.

DYSENTERY AT GALLIPOLI.

SIR,—As one with eight years' experience of dysentery, both from a laboratory and clinical point of view, I would like to endorse the statements put forward by Lieut.-Colonels Ledingham and Wenyon, R.A.M.C., in your issue of July 7th. Having no accurate statistics upon which I can draw, I am unable to speak in quite such an authoritative manner, as regards the proportional incidence of the two main forms of dysentery at Gallipoli, as these two experts are able to do; but I can at least claim first-hand laboratory and a considerable amount of clinical experience of the dysenteries from that theatre of war from the latter part of September till December, 1915, in Mudros; since when up to the present time I have been constantly at work in Egypt on this subject. In my experience the amoebic cases have never exceeded 20 per cent. of the total number—that is, those in whose stools active motile amoebae with ingested red cells were found which could reasonably be regarded as *Entamoeba histolytica*.

In the latter part of September and in the early part of October, 1915, while working in the laboratory at Mudros of Lieut.-Colonel C. J. Martin, F.R.S., the number of stools with active amoebae never exceeded in my experience 20 per cent. of the total examined. During that period bacillary dysentery was rife, as proved both by pathological examination in the *post-mortem* room as well as by isolation of Shiga and "Y" bacilli from the stools during life. With the advent of the cold weather from the middle of October until December I never found active amoebae at all, though *histolytica* cysts were commonly encountered. This tallies exactly with what one would expect from a study of the epidemiology of amoebic dysentery; for the entamoeba is a tropical or subtropical parasite requiring certain atmospheric conditions for its propagation. I am convinced that the practice of diagnosing amoebae in a defunct state, as is sometimes done in stools, where they are supposed to have been rendered non-motile by cold or by the action of emetine, is almost an impossibility, for the dead amoeba undergoes degenerative changes which render it indistinguishable from any other cell in the exudate. The bacillary dysentery stool in the acute stage contains as a rule a large percentage of pus cells and other non-motile refractile cells (10 to 30 μ in diameter), which are liable by the uninitiated to be mistaken for entamoebae. These macrophage cells, as they appear to be, have been described and figured by me in a research I carried out in Fiji in 1910.¹ They have previously been noted by Dutcher² and by Jürgens.³

Lieut.-Colonel Wenyon, R.A.M.C., in his recent papers,⁴ has added to our knowledge of their structure. They

often contain ingested red blood cells and polymorphonuclear pus cells. In microscopic sections of bacillary dysentery intestines I have been able to demonstrate these cells in the submucosa. I have had considerable experience during the last seven years of dysentery epidemics both in the Pacific and in Ceylon, and I am also familiar, through association with the Tropical Diseases Bulletin, with the recent literature on the subject, yet I have never heard or seen an epidemic which was entirely amoebic in origin. It may be that there is a seasonal variation, and that this accounts for the undoubted greater prevalence of amoebic dysentery in Gallipoli during the hot weather, but from the facts I have recorded I cannot believe that the amoebic was the only form of dysentery during the earlier parts of the campaign.

This statement is borne out by the proportionately small number of cases of hepatic abscess and hepatitis of amoebic origin which have occurred since that date.

During the last nine months I have had experience of dysentery as it occurs amongst the Turkish prisoners of war, both from Sinai and from the Hedjaz, and I have proved a large number (some seventy) to be cases of chronic bacillary dysentery by pathological and bacteriological examination, and during that period I have only seen two clinical cases of amoebic dysentery in Turks during life. There have been no amoebic lesions *post mortem*. It would appear, then, that amoebic dysentery is, on the whole, a comparatively rare disease in the inhabitants of the Middle East when subjected to similar conditions, as were our troops at Gallipoli.

As regards Sir R. Ross's advice on the indiscriminate hypodermic injection of emetine regardless of laboratory diagnosis, I consider this practice as an unsound one, and I am convinced that the administration of emetine in large doses as a routine measure to bacillary cases has a prejudicial effect. Acute cases of bacillary dysentery are unfortunately common. They require specific treatment with large doses of polyvalent antidyenteric serum, preferably intravenously administered, to combat the toxæmia in the early stages, and, if necessary, intravenous injection of saline to replace the fluid which is lost by the bowel; all this a too implicit faith in emetine precludes.

Acute and rapidly fatal cases of amoebic dysentery are, in my experience, rare, and die, not from toxæmia, but from perforation of the large bowel and consequent peritonitis.

Whenever an urgent case of dysentery occurs in which no laboratory diagnosis can be obtained, and in which, from a clinical point of view, the diagnosis is uncertain and rapid action is necessary, then there can be no harm, as I have already advocated,⁵ to treat the patient with emetine and antiserum at the same time until the acute stage is passed. The general measure of supplying saline to replace the lost fluid surely applies to both diseases.—I am, etc.,

PHILIP BAHR, M.D., M.R.C.P.,
Captain R.A.M.C.

Cairo, Aug. 8th.

SIR,—My attention has been called to a letter from Lieut.-Colonel Ledingham and Lieut.-Colonel Wenyon in your issue of July 7th. The authors of this letter make definite statements as to the overwhelming preponderance of the bacillary form of dysentery in the Eastern theatres of war; they state that "the extent of the participation of pathogenic entamoebae in the causation of acute dysentery has been very precisely defined" and "that there is no evidence that they (pathogenic entamoebae) have been responsible for more than 20 to 25 per cent. of the acute dysenteries in any area."

These assertions in so far as they refer to the Gallipoli epidemics are not borne out by the published reports. Until these reports are collected and reviewed it would surely be better to avoid making statements which tend to revive the old controversies of amoebic and bacillary schools. Positive protozoological and bacteriological findings are not compatible. I endeavoured to demonstrate this in a paper on the Gallipoli epidemic published in the *Quarterly Journal of Medicine*, April, 1917. This point of view is also referred to in a paper by Captain David Thomson and Captain T. J. Mackie in the *Journal of the R.A.M.C.*, April, 1917. My view that the amoebic ulcers in the colon of the Gallipoli cases were frequently the site

⁴ *Journ. of the R.A.M.C.*, No. 2, vol. xxviii, p. 174.

⁵ *BRITISH MEDICAL JOURNAL*, 1914, i, pp. 294-295.

of secondary bacterial infection is strengthened by Ledingham and Wenyon's statement concerning dysentery in Mesopotamia. They state that "in Mesopotamia 15 per cent. only were amoebic, whilst the examination of convalescents in India produced the impression that amoebic was the predominant type in Mesopotamia."

I would suggest that here also amoebic ulceration of the colon is common; that the acute exacerbation of the disease is frequently due to a secondary infection, and that the amoebiasis was not detected, in some of the cases, until the patients were convalescing in India. I have recently, amongst a number of malaria cases from Salonica, come across twelve patients with *tetragena* cysts or vegetative entamoebae in their stools. Their condition of post-dysenteric colitis is undoubtedly due to amoebiasis, though I do not doubt that they were correctly diagnosed at Salonica as infected with "dysentery bacilli." Had they had specific antiamoebic treatment in the early stage of their colic ulceration, it is possible that their colons would not be in their present unhappy condition. I would emphasize that amoebiasis, like syphilis or malaria, is as a rule amenable to specific treatment in its early stages, but is difficult to cure in its late stages. Amoebiasis is unfortunately present amongst the troops on all our fronts. A most interesting "contribution to the study of dysentery" by A. C. Inman and D. G. Lillie appeared in the *Lancet* of April 7th. They found 97 carriers of *E. histolytica* cysts in convalescent dysenterics from France and Flanders; the blood of 26 of these cases agglutinated Flexner's bacillus, and in 9 the blood agglutinated Shiga's bacillus; they got similar mixed infection results in cases from the Mediterranean and Mesopotamia. Findings such as this make one realize that it will be a serious mistake to underestimate the frequency of amoebiasis and mixed infections.

In determining the correct treatment in epidemics of dysentery one point is definite; if amoebae are the infecting organisms, the earlier the administration of the specific treatment the more likely is that treatment to be successful; there must be no delay. I would suggest, therefore, that if amoebiasis is found to be common amongst the troops emetine should be given as a routine procedure in all cases of dysentery.

In spite of the "ever-increasing laboratory organizations on the Eastern fronts," I know that it is impossible for the pathologists of general hospitals to make repeated and thorough examinations for specific amoebae and dysenteric bacilli in all cases of dysentery. If the pathologist's tastes are mainly bacterial he will devote his attention to culturing faeces and agglutination tests; not perhaps fully realizing the truth of Inman and Lillie's conclusion "that a positive bacteriological or serological finding does not preclude the necessity for a careful protozoological examination."

In Egypt, during the Gallipoli epidemic, we found that amoebiasis was extremely common. I found amoebic lesions in colon or liver of 39.4 per cent. of all necropsies. Amoebic lesions were found in 91.8 per cent. of the cases of dysenteric ulceration of the colon which came to the post-mortem room. This frequency of amoebiasis is confirmed by other observers. Captains Archibald and Hadfield state that at Mudros East 362 out of 518 dysenteric stools were amoebic. Captain Campbell at Cape Hellas found 65 per cent. of the stools with blood and mucus contained amoebae.¹ Lieut.-Colonel Wenyon and Captain F. W. O'Connor, investigating "healthy" men in camps at Alexandria some time after the peninsula was evacuated, found 5.3 per cent. of "carriers of *E. histolytica*."² Seeing the frequency of amoebic infection and of amoebic ulceration of the colon we would surely have been rather foolish had we not adopted the routine administration of emetine as part of our treatment of dysentery. One wonders what the critics would have said had we not given it. Lieut.-Colonel Wenyon showed that in Hadra Prison, Alexandria, 13.5 per cent. of the natives were infected with *E. histolytica*; in the event of a dysentery epidemic in that prison would he not give emetine as part of his routine treatment?

I think that clinicians, realizing that there are considerable gaps in knowledge of the pathogenesis of dysentery, will agree that we should not have been justified in with-

holding emetine from the cases in Gallipoli. Ipecacuanha, or its later derivative, emetine, has long been an empirical treatment for dysentery in all parts of the world. The good effects of the early administration of emetine in Gallipoli were, as mentioned in my paper, indicated by the improved condition of the patients on reaching the base after such treatment had been made a routine. Until exact knowledge is obtained concerning the infecting organism or organisms in epidemics of dysentery such empirical treatment is the only rational treatment.

In conclusion, I venture to state that in determining scientifically the relative preponderance of amoebic and bacterial infections the detection of specific histological lesions in the intestines must take precedence of the results of examinations of faeces; further, if conclusions are to be drawn scientifically from serological examinations, serological tests, which are as reliable as those for bacterial infections, must first be discovered for amoebic infection.—I am, etc.,

G. B. BARTLETT,
Captain R.A.M.C.

"THE PSYCHONEUROSES OF WAR."

SIR,—In a review published under the above title in the *BRITISH MEDICAL JOURNAL* of September 15th, p. 361, the following statement occurs: "Out of his cases [Dr. Eder's cases of psychoneuroses] 70 per cent. were without any family or personal nervous instability, whereas in the remaining 30 per cent. there was such evidence; these results agree with those of Elliot Smith, but differ from those of Mott, Forsyth, Roussy, Lhermitte, and others."

I should be glad if you would permit me to point out that I have never given any figures such as your reviewer attributes to me. In a lengthy review of the little book on *Shell Shock*, written by Mr. Pear and me, Sir Robert Armstrong-Jones in *Nature* of September 7th gives somewhat similar figures as his experience—that is, he claimed to have obtained evidence of heredity as a causal factor in 33 per cent. of his cases, as Dr. Eder has done, but unlike him assumed that such a history might have been obtained in a much larger proportion of cases. But it is hardly justifiable to impute to me the opinions and the figures of a hostile critic.

What I have claimed is that any man, whatever his family history or antecedents, can fall a victim to "shell shock," if he is subjected to sufficiently intense, prolonged, and relevant anxieties and emotional disturbances. But this does not mean that I do not realize the enormous importance of a history of nervous instability before the patient's war experience, whether this was due primarily to inherited weakness or to emotional disturbances during childhood. Another point made by Mr. Pear and me was that even in those cases where a history of neurasthenia, insanity, or drunkenness on the part of the patient's parents was obtained, it was not justifiable to assume that the influence of these conditions was in all cases hereditarily transmitted to the patients whose troubles were being investigated. For the detailed examination of the life-histories of many of such cases revealed the fact that the fundamental element in the development of their condition was some definite emotional disturbance, due to the terrible circumstances to which as young children they were exposed in homes constantly disturbed by irritable or drunken parents.—I am, etc.,

G. ELLIOT SMITH.

The University of Manchester,
September 17th.

THE DISCOVERER OF THE CAUSE OF SLEEPING SICKNESS.

SIR,—Your correspondent, Dr. Nabarro, asserts that to Castellani goes the credit (1) "of having first observed the trypanosome in the cerebro-spinal fluid of sleeping sickness patients." That is true; no one has ever denied it. (2) "Of having first connected it with the etiology of sleeping sickness." That is not true. (3) "Of having first published it." That is also true, but Sir David Bruce wrote the paper published in Castellani's name, and Lady Bruce drew the illustrations which accompanied it.

Your correspondent also appears to be anxious to claim for himself equality with Sir David Bruce in respect of important discoveries concerning the etiology of sleeping

¹ *Journal of the R.A.M.C.*, June, 1916.

² *Ibid.*, January, 1917.

sickness. Those who will take the trouble to look up the history of the subject as given in the *Times* in 1908 and 1913 will see that the claims referred to are as illusory as those put forward on behalf of Castellani, and that the matter is in fact *res judicata*. My purpose has been simply to draw your readers' attention to that fact.—I am, etc.,

London, S.W., Sept. 17th.

E. RAY LANKESTER.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

SIR,—It is simply amazing that the chairman of the Insurance Acts Committee of the British Medical Association (Dr. Brackenbury) writing in the *JOURNAL* of September 15th, can make the statement that the new regulations regarding disabled service men are "entirely different" from those applying to temporary residents. It would appear that either he has not read the regulations or does not understand them.

These disabled men are to be paid for at a dividend rate, which will be the same rate as that for temporary residents of the particular area; it will vary in different areas. The only "promise" made by the Government being that if there is not sufficient money for this in the Invalided Soldiers Fund for the particular area, the deficiency shall be made up. But the essential point of this disingenuous scheme is that not a penny of new money is to be put into the general insurance pool, from which 8s. 6d. is to be taken for every disabled man previously insured.

It will be remembered that according to Memo. 229, I.C. no contribution to the central pool is made for men permanently disabled, nor for those who for the first six months of any year do no work. This, if fair (which we have never admitted) before the war, is now obviously and grossly unjust. It means that panel practitioners, although receiving payment at the rate perhaps of 2s. 1½d. a visit for attendance on disabled men, will receive proportionately less for their ordinary panel patients. It means that practitioners not at present on the panel will be paid directly out of the pockets of panel practitioners.

Can any one deny this? If not, no epithet that I can think of can sufficiently stigmatize these proceedings; nor do I know what to think of the astute financiers that negotiated this and advised us to accept it uncomplainingly.

No man ever enriched himself by taking sixpence out of one pocket and putting it in another, especially if twopence is given to a second party on the way.—I am, etc.,

Croydon, Sept. 15th.

G. GILBERT GENGÉ.

SIR,—In your issue of September 15th Dr. H. B. Brackenbury contributes what he describes as an answer to my letter of September 1st.

But may I remind Dr. Brackenbury a controversy is not much furthered by merely stating that your opponent's arguments "are based upon complete misunderstanding and seriously imperfect knowledge" of what he is talking about? I will endeavour to keep clear of any such mistaken methods of controversy, though of course it is temptingly easy to reply by merely telling your opponent he is wrong.

Dr. Brackenbury says I have completely misread the nature of the proposals with regard to the treatment of discharged disabled soldiers and sailors, and in support of his assertion he says "they are not due to the innate wickedness of the Council"—I never said they were—I attributed them quite distinctly to far other causes. He adds, however, that they are "the outcome of specific resolutions of the last conference of Panel Committees."

There I am afraid I must fall for a moment into Dr. Brackenbury's controversial methods and flatly contradict him. They are not the outcome of any resolutions passed at any conference of Panel Committees, and they were never brought before any single Panel Committee; and further, I challenge Dr. Brackenbury to quote any resolution of any conference sanctioning the proposed terms.

His next assertion is "they do not provide that these men shall be attended under the same regulations as those at present applying to temporary residents."

I again assert that they do provide—and that Dr. Brackenbury and everyone else who has read them knows that they provide—that these men shall be attended in all

particulars that affect practitioners—namely, the terms of payment and the furnishing of accounts—under the same regulations as those applying to temporary residents. Further, I do assert, in common with hundreds of others, that the keeping of these accounts has been proved to be, and will be, a hardship. The few remaining panel practitioners will all be overworked in the coming winter, and it will be found to be an almost intolerable hardship to have this heavy amount of additional book-keeping put upon them.

Next comes the touching argument to prove that my remarks are "based upon complete misunderstanding and seriously imperfect knowledge." It would appear that the unfortunate British Medical Association had the awful labour of taking *seven* diplomatic steps, instead of three, as I so cruelly asserted! The seventh of these laborious steps becomes, however, whittled down when we read that it was "the issue by the Commissioners of the regulations"! The first step, by the way, cannot be passed over without remark: "Persuading the Commissioners that there was a case for increased payment for these cases at all"! It would be interesting to know what were the subtle and cogent arguments which had to be employed to convince the innocent and guileless Commissioners that there was a difference in the insurance risk undertaken by practitioners in the case of strong, healthy working men in the prime of life, and in the case of the same men returning ill, broken, and disabled. I think that even one so singularly lacking in apprehension as I would appear to be, might find one or two arguments bearing upon that abuse point.

Dr. Brackenbury ends his letter by saying that the Association hopes to go one better than my suggestion, and ask for a capitation fee of 10s. not for disabled soldiers only, but for *all* insured persons, and he wants to know will I help. I will help—I have helped; but I doubt if I shall wait for Dr. Brackenbury and his friends to get going. Perhaps a circular issued by the Emergency Committee of the Gloucestershire Local Medical and Panel Committee about ten days ago has not met the eye of Dr. Brackenbury? I beg to add a copy of it for his information:

It has been suggested by the Emergency Committee of the Gloucestershire Local Medical and Panel Committee that a demand should be made that the capitation payment for insured persons shall be 10s., exclusive of medicines, and that in the event of this being refused that work under the Insurance Act should be declined by the panel practitioners of the United Kingdom.

That is the circular which has been sent to every Panel Committee in the country, and I would strongly commend it to the notice of Dr. Brackenbury and his friends, who may perhaps be tempted to await the Greek Kalends before they act.

The witty remark of a labour leader last week is not inapplicable; he said, "the time to act is while there are three jobs to one man, not when there are three men to one job," as it will be after the war.—I am, etc.,

Gloucester, Sept. 17th.

J. A. BELL.

SIR,—Dr. Brackenbury says, in his letter to the *JOURNAL* of September 15th, that Dr. Bell has misstated the conditions offered by the Insurance Commissioners, but does not give the correct terms; may I appeal for the publication of the official documents instead of recriminations that are of no interest whatever to the members of the profession? If you have a weak case . . . etc. The note in the *SUPPLEMENT* is quite uninformative.

Dr. Gardner in his letter speaks of ". . . some sentimental talk by Dr. Brackenbury about a continued low rate of remuneration being the contribution of the medical profession to the war." Very kind indeed of him to arrange our charities for us, but some of us may resent it. I was under the impression that the object of the Insurance Committee was other than that of almoner to the profession.

Dr. Brackenbury says the Treasury asked for data, and the inability of the Committee to produce them was against us. Did not the chairman point out that we could not give statistics of the future, but that the Insurance Commissioners had data of the work done in the past, and that if these were consulted we believed they would support fully our desire for better pay for insurance work?

I want all information published, and I want evidence

that our interests are fully looked after; otherwise it is a case of seeking protection from our friends.—I am, etc.,

Mumbles, Sept. 15th.

F. DE COVERLY VEALE.

* * * An explanatory statement on the above subject is printed under Current Notes in the SUPPLEMENT this week.

MINISTRY OF HEALTH.

SIR,—Captain H. B. Morgan's letter in the JOURNAL of September 1st expresses what I believe are the views of the majority of doctors on war service, whether members or non-members of the British Medical Association. The decision of the Representative Meeting cannot voice the calm and deliberate judgement of the medical profession, because one-third are on war service. Those who are not have not been able, owing to excessive claims in doing extra work, to study all the vital matters involved. Why rush matters? Let us wait and have the judgement of those whose futures are most concerned in this matter.—I am, etc.,

Blackpool, Sept. 5th.

JNO. BROWN, M.D.

QUO VADIS?

SIR,—Disputants in the columns of the JOURNAL naturally expect the observance of the accepted conventions of debate. It may, therefore, be hoped that Dr. Rawdon Wood does not mean what is implied in his letter in the JOURNAL of September 15th. In a previous letter he had called on the officials "forthwith" to publish the evidence in their possession as to the truth or falsity of the statement that the Government had ready a whole-time service scheme and were prepared to work it." I have not yet seen any such evidence, which, according to Dr. Wood, "has finally exploded the myth of Mr. Lloyd George's whole-time service scheme." If any such evidence exists, let it be produced forthwith by all means. Until it is produced those of us who have not seen the evidence are led by Dr. Wood to assume that information of the utmost value to members of the Association was withheld by the "officials," and that many of the present panel doctors were lured to a wrong decision in ignorance of the truth. This is hardly fair to the "responsible officials" on whom Dr. Wood relies for the support of his case.

The negotiations between the Government and the Association in 1912 were necessarily of so confidential a character as to require either complete secrecy or such partial divulgence as the circumstances allowed. Each was fencing with the other—the Government to secure the success of its measure, the Association to secure the status of the profession. Of necessity the contest was unequal. Any Government having the support of a large, solid majority in the Commons is, in a matter of this sectional character, omnipotent. This may not be a palatable truth, but it is a commonplace in politics. On the other hand, the medical profession is a composite body without the elements of cohesion even in so vital a matter as the observance of a standard of honour in the everyday relations between its members. This may also be an unpalatable truth, but it is a commonplace in practice. When, therefore, the Council of the Association undertook the task of mobilizing the profession in its own defence, success depended on inspiring universal confidence, on composing divergent interests, and on imposing rigid compliance with its proclamations. Every meeting of the Representative Body showed that none of these conditions had been secured, and divided counsels led through subterfuge to disintegration. This was the Government's opportunity, and Mr. Lloyd George was not the man to lose it. What followed actually occurred in the manner stated in my last letter, but my information having been obtained in confidence nobody shall ever know its source.

There seems to be no sign that the profession as a whole has taken to heart the lessons of past failure. The groupings which resulted from disorder are already causing dissipation of energy. In view of imminent State developments all the members of the profession, whether attached to auxiliary agencies or not, ought to unite in loyal and consistent support of the Council of the Association. That is the only body recognized by Government as in any real sense representative of the profession, and from that body the profession will in future expect no uncertain answer to its question—"Quo vadis?"—I am, etc.,

Cambridge, Sept. 17th.

B. E. FORDYCE.

SIR,—I trust the buttons are still on the foils if I remark that the fact of Dr. Wood's retirement is more commendable than its manner. He must be aware that I have not refused to accept any evidence, for none has been produced. In company with Dr. Fordyce, I should welcome such production.

On the other hand, as Dr. Wood has entered into private correspondence with me on the subject, he knows that the evidence which I did refer to and accept is at least worthy of consideration, and the witness concerned is of high authority.

As I have before said, readers interested must form their own judgement on our letters, and I am quite content to abide by that judgement. In the years of detachment which lie before him, Dr. Wood will do well to bring his mind under the "disciplinary control" of the generally accepted standards of debate.—I am, etc.,

Cambridge, Sept. 18th.

L. GWILLIM DAVIES.

TREATMENT OF VINCENT'S ANGINA.

SIR,—It is no doubt owing to the exigencies of space that, in his short note on the treatment of Vincent's angina (BRITISH MEDICAL JOURNAL, September 15th, p. 360), Captain Emrys-Roberts omits all mention of our work on the incidence of the affection of the throat and gums due to the fusiform bacillus and spirochaete of Vincent, already published in the *Proceedings of the Royal Society of Medicine* and BRITISH MEDICAL JOURNAL for January and March, 1917, respectively.

He writes of the condition as being widespread amongst our troops and as being familiar, and claims great success in the treatment of these conditions by the use of a mixture of hydrogen peroxide, vinum ipecac., and glycerin.

These substances have long ago been extensively tried by us and have been abandoned for the topical application of salvarsan, and we believe if Captain Emrys-Roberts will follow our directions in using this medicament he will obtain even better results than those obtained by the mixture he so warmly commends.—We are, etc.,

FRANK E. TAYLOR, M.D., F.R.C.S.

W. H. MCKINSTRY, Capt. R.A.M.C.

London, W.C., Sept. 19th.

RUPTURE OF UTERUS.

SIR,—Dr. George F. Riden is to be congratulated on the recovery of his patient reported in the JOURNAL of September 1st (p. 289). As a practitioner of many years' standing, I should like to suggest the following line of procedure in such a case as that described. After rupturing the membranes, wait a while; if the uterus does not contract (provided deformity is slight), give pituitrin or ergot. If progress is not made, apply long forceps. Probably the difficulty was due to irregular contraction setting in, the lower segment of the uterus contracting excessively and collaring the neck, which no amount of traction would overcome without endangering a rupture.

At this stage I would chloroform deeply, then proceed with Smellie-Veit method; that failing, apply forceps to after-coming head. Generally speaking, I find this easy. It would be interesting to have a comment on this case by a higher authority than my humble self.—I am, etc.,

H. DAVIES-JONES, L.R.C.P. and S.Ed.

Mountain Ash, Sept. 3rd.

PAY OF SPECIAL RESERVE AND TERRITORIAL OFFICERS.

SIR,—May I briefly summarize the chief causes of complaint of the R.A.M.C. Special Reserve and Territorial medical officers?

1. The difference between the pay of the temporary medical officer and the pay *plus* all possible allowances of the special reserve medical officer.
2. The great difficulty in obtaining prompt payment of these allowances. This refers to home service; during two years in France I had no difficulty.
3. The loss of all allowances when in hospital, and of some allowances when on leave.
4. The deferred bonus. The temporary medical officer receives £60 at the end of each year, while we receive nothing until the end of our mobilized service.—I am, etc.,

CAPTAIN R.A.M.C.(S.R.).

(Three years' service.)

September 1st.

Obituary.

JOHN ROBERTS THOMSON, M.D., F.R.C.P.,

FORMERLY PRESIDENT, AND AFTERWARDS CHAIRMAN OF COUNCIL,
BRITISH MEDICAL ASSOCIATION; CONSULTING PHYSICIAN,
ROYAL VICTORIA HOSPITAL, BOURNEMOUTH.

We announced last week with deep regret, which will be shared by all who knew him, the death at the age of 73 of Dr. Roberts Thomson, of Bournemouth. He was President of the British Medical Association when it met at Bournemouth in 1891, and was Chairman of the Council of the Association from 1899 to 1901, years during which the reconstruction of the Association was the subject of keen discussion. After the termination of his period of office as Chairman of the Council Dr. Roberts Thomson took no active part in the work of the Association, partly owing to failing health; but he remained a loyal member and watched its development with keen, if sometimes critical, interest.

John Roberts Thomson was born at Slateford, a village a few miles from Edinburgh, on August 24th, 1844. He was educated in Edinburgh, took the diploma of L.R.C.S. Edin. in 1865, in 1866 graduated M.D. of the University of Edinburgh, of which his father before him had been a distinguished member, and afterwards held the appointment of house-physician to the Royal Infirmary, Edinburgh. His connexion with Bournemouth began in 1866, when he applied for a post on the staff of the Royal National Sanatorium. Dr. Snow was a candidate at the same time, and as a result of a tie in the voting both were appointed. He retained his connexion with the institution throughout the remainder of his life and was consulting physician at the time of his death.

At the time when Dr. Roberts Thomson went to Bournemouth it was a small place, although it had already attained considerable reputation as a climatic resort. The nearest station was six or seven miles away, and the place was little more than a village. He saw it develop into a large town, which has been for a good many years a county borough. From an early stage he took an active part in the life of the district, and was a member of both the county and the borough bench and an original member of the Hants County Council. The growth of the town called for the establishment of a hospital, and Dr. Thomson himself related the story when, in 1913, the freedom of the borough was presented to him. In 1866 there was a small dispensary in Bournemouth, but no hospital nearer than Southampton or Salisbury. The first step was to establish a cottage hospital, afterwards merged into the Royal Victoria Hospital, built as the town's memorial to the first jubilee of Queen Victoria. Dr. Thomson's interest in the public life of Bournemouth

extended, however, very far beyond hospital questions. He took a deep interest in education, was one of the founders of elementary schools, and for many years president of the School of Science Arts and Technology, now merged in the Municipal College. He was one of the first members of the Hampshire Technical Instruction Committee, and was chairman of the Bournemouth Committee. During his tenure of that office Bournemouth School was established, and he was appointed chairman of the board of governors, and afterwards he established the Thomson scholarships. So lately as last June he presided at the annual speech day. As a young man in Bournemouth he took a great interest in the volunteer movement, joining the force as captain in 1883. On the formation of the 4th Battalion of the Hampshire Regiment he became major, and was in command of the battalion when it was reviewed by Queen Victoria at

Osborne in 1899. He also attended the review at Aldershot in 1897 on the occasion of the jubilee. During the Boer war he formed three active service sections from the battalion, one of which went out in command of his son. He received the Volunteer Decoration, which was a just recognition of his share in the growth of the regiment and the fine spirit with which it is imbued. Dr. Roberts Thomson was a Liberal in politics down to the time of the introduction of the Home Rule Bill, when he became a Liberal Unionist, and might, we believe, easily have obtained the nomination of the Unionist party for election to the House of Commons had he so desired. He was a staunch Churchman, and president of the Young Men's Christian Association in Bournemouth.

Dr. Roberts Thomson would have been unable to attain the position he reached had he not been a sound practical physician who kept himself well informed in all advances of

DR. JOHN ROBERTS THOMSON.
(Photograph by E. Day and Son, Bournemouth.)

medicine. He did not write much, but he was universally looked up to by the profession in Bournemouth and south Hampshire as a physician and as a man. It was natural, therefore, that when, at the suggestion of Dr. Davison of Bournemouth, who pays a tribute to his friend below, and Mr. Watts Parkinson of Wimborne, it was resolved to invite the British Medical Association to hold its annual meeting in Bournemouth, the local profession should turn to him and invite him to occupy the position of president. The meeting took place in 1891, and as those who attended it will remember, it was extremely successful; the arrangements were complete in every detail, the scientific work was of a very high standard, and there was an energy and go about the meeting which was largely due to Roberts Thomson's own influence. Dr. Thomson devoted part of his address to the consideration of the then position of medical officers of health, and urged that the appointment of medical officers by county councils should be obligatory, a reform

adopted after some years; we still await the realization of another aspiration he then expressed, which was that every part of the kingdom should be "brought into sympathetic communication with the Central Board upon which the medical element shall have real and substantial power."

Dr. Thomson's favourite recreation was mountaineering, a sport in which Mrs. Thomson also excelled, but a few years after the meeting in Bournemouth he met with a very serious bicycle accident which laid him up for many months, and left him with a permanent lameness. This did not, however, induce him to give up his public activities, and in 1899 he accepted election to be Chairman of the Council of the British Medical Association. He held this office during anxious times; many members of the Association had become dissatisfied with its machinery for dealing with political questions, and a Constitution Committee was appointed at the Ipswich meeting in August, 1900. Of his work on that Committee a colleague, Dr. J. C. McVail, has at our request written the following note:

"Dr. Roberts Thomson played a very useful and important part in the deliberations of the Constitution Committee, the labours of which resulted in the end in radical change of the Association's organization. Dr. Thomson was not an advocate of sweeping alterations, but rather the opposite. He was Chairman of Council, and I presume had a natural feeling of loyalty to the system of government then represented by the Council. He was therefore rather by way of defending the best features of the old system, and even though his views were not in the main given effect to, he was of great value throughout the discussions, as it was important that all sides of the question should be considered in arriving at conclusions. In all the work of the Committee, whether or not he was getting his own way, Dr. Thomson was a model of courtesy and urbanity. The same fine qualities characterized him as Chairman of Council, and under his kindly rule it was a real satisfaction to take part in the proceedings. I have the pleasantest recollections of our intercourse both in the Council and in the Constitution Committee, and his death must be a cause of much regret to all who knew him even though some of us may not have met him for many years. Of those who carried on the affairs of the Association at that time very many have departed, and Dr. Thomson was among the most prominent of those who had remained with us until now."

Dr. Roberts Thomson was twice married and leaves a widow, three sons, and a daughter to mourn their loss. The eldest son, Major A. F. Roberts Thomson, is in command of a battalion of the Australian Field Artillery now serving in France; the second son, Lieut.-Colonel William

Roberts Thomson, has been in command of a battalion of the Hampshire Regiment in India since an early stage of the war; the youngest son is engaged in Church Army work in Scotland; and Miss Roberts Thomson is the matron of the Westmorland County Hospital at Kendal.

The funeral, which took place at Bournemouth on Saturday, September 15th, was very largely attended by members of the medical profession and by representatives of the numerous organizations with which Dr. Thomson was connected. The coffin, covered with the Union Jack, was borne to the church on a gun carriage supplied by the Royal Engineers. Among others present were Lord Montagu of Beaulieu, and officers and men of the 7th Hants Regiment, and Colonel Perkins, representing the County of Southampton Territorial Force Association. The British Medical Association was represented by Dr. W. Johnson Smyth, a member of the Council of the

Association, and the Dorset and West Hants Branch by Dr. Frank Fowler and Dr. Charles D. Muspratt, lately its president. The Bournemouth Medical Society was represented by Dr. A. McCall. But formal representation was hardly necessary, as most of the members of the medical profession in Bournemouth and the neighbourhood were present to pay their last respect to an acknowledged leader.

We are indebted to Dr. James Davison, of Bournemouth, who was a friend of Dr. Thomson for so many years in Bournemouth, for the following sympathetic tribute to his memory:

"Suffering at the moment from the shock of the great and irreparable loss I have sustained by the death of my old friend Dr. Roberts Thomson, I feel unequal adequately to do justice to his memory.

"On settling in Bournemouth early in 1883 I became acquainted with Dr. Roberts Thomson.

The acquaintance rapidly developed into friendship, and ever since we have worked together in perfect harmony and closest professional relationship. No semblance even of a cloud ever crossed our path or ruffled our intercourse. He was my senior by some two years. No one could have had a nicer leader, a truer friend, and a more faithful colleague than he was. His accomplishments and activities were very numerous, but he was never happier than when conceiving and maturing schemes designed for the betterment of his fellow men, and the improvement of the town of his adoption, which he loved so well. The welfare of his professional brethren was a matter always near his heart. On questions of ethics, which not infrequently arise, he was ever ready to act as mediator. By kind advice, clear reasoning, sound judgement, and just diplomacy, he was able to adjust thorny controversies to the satisfaction of all concerned.

"Professionally he was a man of varied and extensive

education, high attainments, and profound accomplishments. Had his lot as a physician been cast in a more extensive field than a fashionable seaside resort can offer his fame would have shone with bright effulgence. While his health lasted he was extensively sought after as a consultant in this district and for many miles around. By the public generally he was beloved for his kind and cheery disposition, his goodness of heart, and his deep sympathy with suffering. His charity was abounding yet circumspect and discriminating. Few, if any, deserving people ever appealed to him in vain. His memory will live long in the hearts of all who knew him. His death was as calm and peaceful as his life had been serene and beautiful. Let the earth lie lightly on the mortal remains of John Roberts Thomson, for he was a man of noble parts, an eminent physician, a charming colleague, a friend of mankind, and a gentleman."

SURGEON-GENERAL WILLIAM SIMSON PRATT, C.B., R.A.M.C.(retired), died at Bideford, North Devon, on September 8th, aged 68. He was born on January 21st, 1849, educated at Edinburgh University, where he graduated M.B. and C.M. in 1872, and entered the army as surgeon on April 1st, 1874. He was promoted to surgeon-major in 1885, to surgeon-lieut.-colonel in 1893, full colonel in 1902, and surgeon-general on December 29th, 1905, retiring on January 21st, 1909. He served in the Sudan campaign of 1884-85, when he was mentioned in dispatches, received the medal with a clasp and the Khedive's bronze star, and was specially promoted to surgeon-major. He was made C.B. in 1906. He was principal medical officer at Gibraltar in 1900-02, and subsequently held the same post in the Southern Command.

PROFESSOR JULES COURMONT of Lyons died of cerebral hæmorrhage while making his visit at the Hôtel-Dieu the day after returning from a military mission to the British front. He was born at Lyons on January 26th, 1865, began the study of medicine in 1882, and graduated at the university of his native city in 1891. In 1892 he became *agrégé* and in 1896 physician to the hospitals. He worked for many years at microbiology and general pathology as chief assistant in Arloing's laboratory. In 1900 he was appointed to the chair of hygiene in the University of Lyons, and from that time gave his attention more and more to social questions. He did valuable service to sanitary reform in Lyons and the whole department of the Rhône. He founded a Pasteur institute and an antituberculosis dispensary at Lyons. In 1912, in conjunction with M. Herriot, mayor of the city, now Minister of State, he began to organize an international exposition at Lyons where everything relating to the welfare of the city was to be represented, but the outbreak of war interfered with the fulfilment of the project. Courmont was mobilized and did important work, especially in organizing the hospitals for contagious diseases in the 14th military district. He was a corresponding member of the *Académie de Médecine*, a member of the *Comité Consultatif d'Hygiène de France*, and vice-president of the Superior Council of Hygiene. He was an officer of the Legion of Honour.

PROFESSOR RAOUL LEFOUR of Bordeaux, who died in November, 1916, was born at Chenerrailles in the Creuse. He studied medicine at Bordeaux and afterwards at Montpellier, where he took his doctor's degree in 1875. In 1880 he won the appointment of *agrégé* in the Bordeaux faculty with a thesis on the relations of uterine fibromata to pregnancy and parturition. He quickly made his mark as a teacher and at the same time gained a place amongst the foremost obstetricians of Bordeaux. He was appointed surgeon-accoucheur to the hospitals, and in 1895 succeeded Lugeol as surgeon-in-chief to the Pellegrin Maternity. On the retirement of Moussous in 1898, Lefour succeeded to the chair of clinical obstetrics, which he held for eighteen years. Although his health had been failing for some years, when the outbreak of war called most of his colleagues to active service he insisted on resuming his hospital work. Lefour was the author of several contributions to the literature of his speciality, including a clinical and experimental study of the influence of knots of the cord on the fetal circulation and chemico-biological researches on the blood of the fetus.

PROFESSOR ANNIBALE SALOMONI, of the University of Messina, who died on April 18th, was born at Cremona in 1854. He studied medicine at Pavia and after graduation worked for some time under Billroth in Vienna, and in various other universities. He was appointed professor of surgical pathology at Messina in 1894 and continued to occupy the chair till his death. He was very popular with his professional brethren and with the people of Messina; after the great earthquake he worked day and night among the sufferers, many hundreds of whom he saved from death. On the entry of Italy into the war Salomoni offered himself for military service, and was director of a hospital at Piacenza, where he worked till disabled by illness. He was the author of many publications on descriptive and topographic anatomy, operative surgery and surgical pathology, and of a valuable report on ankylostomiasis in the Cremona district.

DR. CHARLES LIVON, director of the Medical School of Marseilles, died recently at the age of 67. In 1893 he founded the antirabic institute of Marseilles, and since the beginning of the war he has been head of the auxiliary military hospital of that city. He was the author of a manual of vivisections, and of a large work on experimental physiology in three volumes, published from 1892 to 1910.

PROFESSOR PAUL DUPUY of Bordeaux, who lately died at the age of 90, was born in 1827, took his doctor's degree at Paris in 1857, and was appointed professor in the Bordeaux Preparatory School of Medicine in 1864. In 1878, when the school was transformed into a Faculty, he was appointed professor of medical pathology. He wrote on many subjects—medical, political, social, financial, and philosophical. His last book, published in 1911, dealt with Auguste Comte, the prophet of positivism.

The Services.

TERRITORIAL DECORATION.

THE Territorial Decoration has been conferred upon the following medical officers of the East Anglian Field Ambulance: Lieut.-Colonel J. Howard-Jones, M.D., D.Sc.; Major Henry Waite (attached R.E. Signal Service) and Major D. G. Newton, M.B., F.R.C.S. (attached Yorkshire and Lancashire Regiment).

Medical News.

THE Right Honourable Christopher Addison, M.D., M.P., Minister of Reconstruction, will distribute the prizes to successful students of Charing Cross Hospital on Monday, October 1st, at 3.30 p.m.

IN consequence of its declaration of war against Germany the Republic of Cuba has increased its army to 17,000 men. The medical service is being reorganized, and one colonel and twenty other officers of lower rank are to be commissioned.

THE inaugural address at the London (Royal Free Hospital) School of Medicine for Women for the session 1917-18 will be delivered by Dr. Louisa Garrett Anderson, C.B.E., on Monday, October 1st, at 3.30 p.m., at 8, Hunter Street, Brunswick Square. The subject of the address will be Ambition. Academic dress will be worn.

THE opening ceremony of the seventy-sixth session of the School of Pharmacy of the Pharmaceutical Society of Great Britain will be held on Wednesday, October 3rd, at 3 o'clock, at 17, Bloomsbury Square, London, W.C.1, when the Hanbury gold medal will be presented, and Lieut.-Colonel E. F. Harrison, C.M.G., will deliver the inaugural sessional address.

AN announcement by the Ministry of Pensions appears in our advertising columns this week, inviting applications from medical practitioners from Westmorland, Lancashire, and Cheshire, to serve on medical boards for the examination of, and the assessment of pensions for, men discharged from the army for neurasthenia and functional nervous disorders.

SIR FRANCIS LOWE, M.P., and Mr. William Forrest Bowen, President of the Incorporated Dental Society, have been nominated by the Lord President of the Council as additional members of the Departmental Committee appointed

to investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act.

THE New York Board of Health states that the city is apparently free from poliomyelitis. Only 77 cases have been reported this year.

THE *Morning Post* printed on September 19th a translation from an article in the official organ of the Serbian general head quarters, eulogizing the work of the British hospitals on the Serbian front, and expressing gratitude to the British people, who have placed at the disposal of the Serbian army on the Salonica front field hospitals of the most modern equipment with a total of 10,000 beds.

DR. JOHN HENRY BARTLET, senior surgeon and honorary consulting physician to the East Suffolk and Ipswich Hospital, who died on May 27th, aged 87, left estate of the gross value of £272,430, of which £249,709 is net personality. After making provision for a number of legacies he left the residue of his property, exceeding £200,000, to the East Suffolk and Ipswich Hospital for a home of rest for patients recovering from illness.

ACCORDING to the *Medicina Practica* of August 31st, in an air raid over the Romagna the Austrians threw sweet meats, which Dr. Pizzo Zanotti, director of the laboratory attached to the municipal bureau of hygiene at Ravenna, found to contain cultures of pathogenic germs. Most of these were dead, probably owing to desiccation, but in the fresh state they were capable of causing most serious infections.

A FRENCH Society of Urology has been formed under the patronage of Professor Guyon. Its true begetter is Professor Leguen, whose object, as set forth by himself, was to gather together the scattered forces of urology in France into a compact unit which is to fight scientifically, honourably, but energetically against the pretensions of German workers. The society, membership of which is to be exclusively French, will meet once a month in the buildings of the Faculty or at the Necker Hospital.

As the result of a preliminary consideration of the reports on the physical welfare of mothers and children recently presented to them by the special inquirers they had appointed, the Carnegie United Kingdom Trustees contemplate the acquirement or erection of a suitable building in London for the housing of a central institute to serve as a co-ordinating agency for the various organizations connected with infant and maternal welfare in England and Wales, and of a similar central institution in Scotland. As an experiment and to stimulate local effort, the Trustees will select certain urban areas in which they will be prepared to meet the cost of the erection and equipment of model welfare centres to be controlled and maintained by the local authority with the aid of imperial grants. The Trustees will also consider favourably in a few instances applications from local authorities for help toward the initial capital outlay on open spaces for children's playgrounds which the authorities may have acquired and are prepared to maintain. The Trustees hope in these ways, during the next three or four years, to employ the limited fund at their disposal in promoting a few well-devised experiments in organized effort towards the solution of a grave national problem.

KÜSLER AND GÜNZLER (*Centralbl. f. Bakt.*, I Orig., Bd. 78, p. 442) report the results of the employment of the proprietary antiseptic "sano" by inhalation for the treatment of carriers of the meningococcus and the diphtheria bacillus. Its chief active constituent appears to be sodium hypochlorite but it contains borax also. This constitution may be compared with that of Dakin's solution, which contains chlorinated lime, sodium carbonate, and boric acid. The solution was converted into spray by means of an apparatus, superheated steam being employed as the nebulizing agent. From the description and the figure in the text the apparatus would appear to be that of Wassmuth, which Gordon and Flack found to be inferior to their own instrument (*BRITISH MEDICAL JOURNAL*, 1916, vol. ii, p. 673). Küsler and Günzler state that with the apparatus they used a very fine state of division is produced and that the working was economical. Spray derived from a solution containing 2.3 parts of chlorine per 1,000 could be inhaled for several hours without causing irritation; on the other hand, the inhalation of spray of an ordinary sodium hypochlorite solution containing 2.39 parts of chlorine was found to be irritating to the respiratory tract. It was found that in the case of meningococcus carriers, the inhalation of a spray of the solution containing 2 parts of chlorine per 1,000 for one hour on each of three successive days led, in most cases apparently, to a permanent disappearance of meningococci from the nasopharynx. The observations on diphtheria carriers were too limited to be of much value.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Offices, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are: (1) EDITOR of the *BRITISH MEDICAL JOURNAL*, Aitiology, Westrand London; telephone, 2531, Gerrard. (2) FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate, Westrand London; telephone, 2530, Gerrard. (3) MEDICAL SECRETARY, Matiseira, Westrand, London; telephone, 2534, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

LETTERS, NOTES, ETC.

DERMATITIS FROM UNCLEAN TOOTH-PLATES.

DERMATOLOGIST writes: Skin eruptions are sometimes caused through tooth-plates not being properly cleansed with soap and a suitable brush. Mr. J. G. Turner, in writing on dental sepsis in the *JOURNAL* of June 13th, 1914, said the best brush made, though big and ugly, is well chosen. This brush can be obtained from Messrs. Ferris and Co., Union Street, Bristol.

INFANTILE DIARRHOEA.

A CORRESPONDENT who has had a good many years' experience of general practice desires to impress on all young medical practitioners that in dealing with the worst forms of acute febrile diarrhoea in infants "the cardinal fact is that the poison is usually in the milk given, which in the warm summer months has been bacteriologically contaminated." The cure, he says, consists in cutting off the supply of all forms of milk food for a few days and feeding the infant on bland fluids freed from milk. This is sound teaching. The common belief that an infant will collapse if deprived of nutriment for a few days, though very natural, is erroneous. During the acute stage the digestive processes are wholly, or almost wholly, suspended, and the stomach and intestines need rest. Our correspondent advises resort to mutton tea, made in the same way as beef tea, or white of egg water or barley water, in suitable cases, but pure water will often serve the purpose quite as well. The great point, as our correspondent says, is to avoid milk and all milk preparations. He adds that if a wet nurse can be obtained the infant may usually safely have the breast milk.

BRITISH HEALTH RESORTS.

DR. T. D. LUKE (St. Romans, Venlaw Brae, Peebles) writes: I was asked some time ago to prepare for Messrs. A. and C. Black a guide to British health resorts, endeavouring as far as possible to bring into prominence the many attractions which our own country offers in the way of first class spas and seaside resorts. Apart from the well-known spas, however, there are many wells and springs scattered through the country which have at least a local repute and are of some historic interest. I shall be very grateful to any members of the profession who will send me details of any such wells, etc., in their district so that the chapter on this subject may be as complete and informative as possible. All our big spas had small beginnings, and who knows, some of these at present neglected sources of mineralized water may be of value, and blossom out into health resorts. It is at any rate believed and hoped that once the great war is over most people will think twice before taking a far journey to Germany and leaving money there which could with equal benefit and greater propriety be spent at home. No one who was "caught napping" at Nauberg, Homburg, Kissingen, or Wiesbaden at the end of July, 1914, will willingly enter Germany again in search of health. That is pretty certain.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postea* letters addressed either in initials or numbers.

Observations

ON

THE ETIOLOGY AND TREATMENT OF
WAR NEUROSES.

BY

ARTHUR F. HURST, M.D., F.R.C.P.,

TEMPORARY MAJOR R.A.M.C.,

PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL; NEUROLOGIST
TO THE ROYAL VICTORIA HOSPITAL, NETLEY.I.—EXHAUSTION RESULTING IN NEURASTHENIA
AND SOLDIER'S HEART.

ETIOLOGY.

ALTHOUGH it would require a very exceptional nervous system to pass unscathed through twelve months or more of war under modern conditions, uncomplicated neurasthenia due to prolonged physical strain, the utter nervous exhaustion caused by pure physical fatigue, has been comparatively rare since the battle of the Marne. But there were many cases after the retreat from Mons, and it says much for the spirit and discipline of the original Expeditionary Force that there were no more.

Life in the trenches is always accompanied by a state of nervous tension. Danger is ever present, and during periods of activity the night may only bring increased responsibility and anxiety instead of rest. Although most men become gradually accustomed to the sights and sounds, which at first frighten all but the few who do not know what fear is, the nervous system does not wear well, and unless regular periods of rest from the mental strain are given, the majority of men gradually become irritable, restless, and unable to perform their duties satisfactorily.

The sanitation of the army in France has been so efficient that the second great cause of neurasthenia—acute and chronic infections—has been less prominent than in any previous campaign. But comparatively slight toxæmia, such as that due to diarrhoea, trench fever, or influenza, which is not sufficiently severe to make a man go sick, may cause nervous exhaustion, which would have been prevented if sufficient rest had been taken.

The armies in other parts of the world have, unfortunately, not shared the immunity from serious epidemics with the army in France. Few men remained at Gallipoli for more than a month without suffering from chronic diarrhoea or falling victims to dysentery, paratyphoid fever, or epidemic jaundice, and often to more than one of these infections at the same time; added to this was the impossibility of withdrawing the troops from the shell-swept area, for every corner on the peninsula was exposed to hostile fire. In Salonica conditions were more favourable, except during the summer of 1916, when the hot weather and the virulent form of malaria for which the Struma Valley has always borne an unenviable reputation were the chief causes of many cases of neurasthenia. The effect of the numerous infections rife in Mesopotamia and East Africa has been aggravated by the great heat, and at times by the insufficient supply of food. During the autumn of 1916 the majority of uncomplicated cases of neurasthenia reaching England came from Mesopotamia; in several cases there was a history of actual heat-stroke.

The pain, toxæmia, and loss of blood which may result from severe septic wounds often cause neurasthenia, especially if the soldier is already over-fatigued from mental and physical strain.

Mental and physical strain, severe pain, and acute and chronic infections lead to exhaustion by their direct action upon the nervous system, and indirectly by their action upon the suprarenal glands, together with the liver and probably the thyroid. Prolonged muscular exertion and great emotions, especially fear and anger, have been shown to produce chromatolysis of the brain cells, together with definite changes in the suprarenal glands and liver.

SYMPTOMS.

The symptoms of neurasthenia in soldiers do not differ from those of the neurasthenia of civil life. Headache, rapid fatigue on mental and physical effort, and difficulty in concentration are always present. The appetite often remains excellent and the digestion good, but constipation is common. The symptoms described under the name of

"soldier's heart" may be prominent. In most cases the blood pressure is low, corresponding with the fact that the blood pressure of the average tired soldier in front line trenches is slightly subnormal.

TREATMENT.

Complete physical and mental rest are at first essential. The patient must be kept in bed until he no longer feels tired. In slight cases a week or fortnight may be enough, and it is rarely necessary to continue the complete rest for more than three weeks, though in severe cases two or three months may be required, especially after severe infections. In most cases a small dose of bromide, such as gr. v, is given two or three times a day. Opium must be avoided, as it often aggravates the symptoms and increases the excitability and restlessness of the patient. No alcohol should be allowed; it is very badly tolerated by almost all patients suffering from war neuroses, and especially from true shell shock. A quantity which formerly produced no ill effect is often sufficient to intoxicate. Recovery is greatly accelerated by combating insomnia, as the exhaustion cannot disappear so long as the patient sleeps no more than three or four out of the twenty-four hours. I have found sodium diethyl-barbiturate (medinal) with acetyl salicylic acid (aspirin) gr. xv the best combination. The dose of the former should be between 10 and 15 grains the first two nights, after which it should be reduced by 1 grain every other night until only the latter is given, and the dose of this can then be gradually reduced. In intractable cases, especially if nightmares are present, suggestion under hypnosis is very effective.

As soon as the patient is well enough to get up he should begin to help in the ward, and a few days later he should be given light employment out of doors, for

The cure for this ill is not to sit still
And frown with a book by the fire;
But to take a large hoe, and a shovel also,
And dig till you gently perspire.

The amount of exercise should be gradually increased, and the patient should not be discharged from hospital until he can do moderately heavy work, such as digging, without undue fatigue.

II.—EMOTIONS RESULTING IN STUPOR AND AMNESIA,
PSYCHASTHENIA, HYSTERIA, HYPERADRENALISM
AND HYPERTHYROIDISM, AND EXAGGERATED
DEFENSIVE REFLEXES.

The emotion produced by a very horrible incident, such as seeing a friend killed whilst talking with him, is sometimes sufficient to give rise to nervous symptoms. More commonly, however, such an event is only the culmination of a long series of emotional storms. In most cases, indeed, the final breakdown is not due to a definite incident, but is the result of the cumulative effect of fear, which gives rise to symptoms sooner or later or not at all, according to the temperament and the physical condition of the individual. It is often impossible to obtain an accurate history of the onset until the patient is convalescent, as in the early stages of his illness he is generally unwilling to talk about his experiences. Even after complete recovery, a horrible incident which was the exciting cause may remain obliterated from the memory, although it may have returned in dreams, or its nature may have been elicited from the patient during hypnosis.

(a) STUPOR AND AMNESIA.

The stress and strain of active service not infrequently result in a condition of mild confusion, which may merge into deep stupor. The onset is often gradual. A man who has hitherto been alert and efficient becomes more and more dull, slow, and silent, until finally—often after an incident which has caused unusually great terror or horror—he becomes too confused to carry on, and he may wander away from his unit in a condition of stupor with more or less complete amnesia. Exactly the same condition may follow actual shell shock, but many cases which on reaching hospital without any history are at first diagnosed as shell shock later prove to be simply the result of emotion. It may also follow simple exhaustion, or it may represent an epileptic attack. In severe cases the man remains for a time entirely unconscious of his surroundings. He appears not to see or hear, he cannot be induced to speak, and pinching his skin produces no response. The reaction of the pupils to light is impaired or lost. He does

not ask for food, but chews and swallows whatever is given him. He lies inert, and involuntary micturition and defaecation are frequently present during the first few hours. Complete insensibility is often followed by a dazed condition, in which automatic complex acts may be performed. A man may be found several miles away from his unit, but he will never recall how he covered the distance.

The duration of stupor varies from a few minutes to several days, but it rarely lasts more than a week. It may suddenly pass away, the patient having no recollection of what occurred between the onset and the moment of recovery. More frequently improvement is gradual.

(b) PSYCHASTHENIA.

Prolonged mental strain may give rise to the purely mental symptoms, which can be most conveniently grouped together under the name of psychasthenia. The most important and common of these are nightmares and day-dreams; obsessions and phobias are less common; ties are curiously rare. Nightmares are very common, and many men live through their most terrifying experiences night after night in their dreams. In some cases the dream is forgotten, the patient only recollecting that he woke with a start and found himself in a cold sweat. The disturbed nights caused by war-dreams almost invariably result in headache, which is worse in the morning and only disappears towards evening. Many patients resist the desire to sleep during the day, as they fear a recurrence of their dreams, or they think that sleeping in the daytime will make their nights still less restful. A condition of profound exhaustion may ensue, and the patient loses his appetite and feels intensely depressed. In severe cases the dreams may recur during the day whilst the patient is apparently awake.

Unaccustomed responsibility may give rise to obsessions or phobias in men whose resistance has been lowered by the strain of prolonged service at the front, or who are predisposed by having had a mental breakdown, or by having a family history of mental disorder.

I have seen a few cases in which ties have developed during active service; in most instances they have been associated with hysterical symptoms, and the patients have often previously suffered from ties. One man developed a side-to-side movement of his head, the original object of which had been to relieve the pain caused by concussion of his cervical spine. He could only control it for two or three seconds, and it persisted during light hypnosis, but not during sleep.

Treatment.

The general treatment of a man suffering from psychasthenia is identical with the treatment for neurasthenia. In slight cases nothing more is required, but special treatment is generally necessary for the more prominent psychasthenic symptoms.

In some cases a nightly dose of acetyl salicylic acid with medinal, the dose of which is gradually reduced, as described in the treatment of neurasthenia, will lead to the cessation of nightmares. But when a dream has persisted for any length of time, nothing but hypnosis will remove it. This should, if possible, be practised at night, so that the patient can pass from the hypnotic state into natural sleep, the suggestion being repeatedly made that he will not dream. A single treatment is often sufficient, and it is rarely necessary to repeat it more than five or six times.

Phobias and obsessions sometimes disappear after rest and "therapeutic conversations," in which the cause of the symptoms is explained to the patient, and he is encouraged to hope that they will quickly disappear as his general condition improves. It is of the utmost importance that his confidence should be gained, and that he should feel that he can discuss his troubles with perfect freedom and without any fear of being misunderstood. In severe cases, and especially when the phobia or obsession is of a very distressing character, suggestion under hypnosis should be employed without delay. The result is generally very satisfactory, and improvement often occurs with remarkable rapidity.

Ties are more resistant to treatment, as they tend to persist after the other symptoms have disappeared, and though they rarely continue during hypnosis, suggestion has comparatively little effect upon them. Re-education is the most valuable treatment. Regular exercises are

given for the affected muscles, and in order that complete control may be regained over them the patient is made to inhibit the movements several times every day by an effort of will for a certain period, the duration of which should be slowly increased. I have seen several soldiers with aerophagy and eructation ties, who were cured by clenching a stick between the teeth whenever the desire to eructate was felt.

(c) HYSTERICAL SYMPTOMS.

Hysterical symptoms may develop as the immediate result of a strong emotion, the physical results of which become perpetuated and exaggerated by auto-suggestion. Sudden extreme terror causes inhibition of activity instead of the physical preparation for flight, which is produced by the sympathetic and suprarenal stimulation following more prolonged but less excessive fear. The knees give way, the breath is held, and the "tongue cleaves to the roof of the mouth," rendering speech impossible. These are perhaps manifestations of the instinct to hide, as, when flight is impossible, recourse must be taken to concealment.

The inability to move or speak under these conditions is in most cases only momentary. But a man whose nervous system is already suffering from the strain of active service may be so suggestible that the incapacity is perpetuated and exaggerated, when he realizes that he is physically unable to escape from his terrifying surroundings or call for help, and the possibility that this inability may be permanent and not merely a thing of the moment flashes through his mind. True hysterical paraplegia or mutism is the result.

It is much more common for an interval to elapse between the incidents which gave rise to the emotion and the onset of symptoms. It is thus very rare for hysterical symptoms to develop actually in the trenches. They are comparatively common in casualty clearing stations, and still more so at base hospitals. Not infrequently the hysterical symptoms only appear after the patient has arrived in England. In the dazed condition which results from prolonged mental strain a man is abnormally suggestible; his critical faculties are lost and initiative is diminished. As he gradually comes to himself he tends to exaggerate and perpetuate the difficulties he experiences in the performance of the various functions of his body. The absence of movement due to absence of initiative leads to the suggestion of paralysis, the silence due to absence of any desire to speak in his confused mental condition suggests mutism, and the inattention which prevents him hearing what is said to him suggests deafness. Under these conditions hysterical symptoms may be caused by circumstances which rarely if ever lead to them in civil life. Thus I have twice seen hysterical paraplegia follow an operation for acute appendicitis which had developed in the trenches, and develop after an attack of malaria and of cerebrospinal meningitis, and in several cases after muscular rheumatism. Hysterical paralysis of a leg followed trench fever in one case and paratyphoid arthritis of the hip in another, and hysterical hemiplegia which lasted for two years followed an attack of sunstroke. In these conditions the temporary incapacity caused by the pain or the weakness associated with the primary illness was sufficient to give rise to the idea of paralysis.

In their chief characteristics there is nothing peculiar about the hysterical symptoms which occur in soldiers, whether as a sequel of an emotion, true shell shock, an injury due to a wound, or some acute illness. But they are so common that in two years I have seen more cases among soldiers than I had seen in men, women, and children in the previous ten years. It is not surprising, therefore, that hysterical manifestations are occasionally seen in soldiers which differ from anything which one has seen or heard of in civilians, but the one invariable feature of all cases, both in peace and in war, is their production by suggestion, and their curability by suggestion or persuasion.

Treatment.

Hysterical symptoms in soldiers have proved very amenable to treatment. Some cases sooner or later recover spontaneously, but others show no tendency to improve if left to themselves, and I have seen several cases of hysterical paraplegia, dumbness, blindness, and deafness,

which had persisted for many months, sometimes for over a year, and which would almost certainly have remained permanent if vigorous treatment had not at last been instituted. As it is impossible to tell when the patient is first seen whether spontaneous recovery will take place, active treatment should be given immediately. Thus large numbers of men can be sent back to the firing line within a few days of the onset of symptoms if treated at casualty clearing stations, and hysterical symptoms should rarely persist for more than twenty-four or forty-eight hours after admission to a hospital in England. The longer hysterical symptoms are allowed to remain the more difficult they are to cure. Although immediate improvement generally results from correct treatment, even in cases of very long standing, complete recovery is less easy to obtain; a man who recovers from hysterical paraplegia within two or three weeks of the onset often walks normally within an hour of the commencement of treatment, but his gait may remain abnormal and require careful re-education for many weeks if the paraplegia has been present for a longer period. Similarly early treatment of mutism is followed by rapid and complete recovery, but if left too late the patient whispers or stammers when he regains his power of speech, and often needs prolonged re-education before he can talk normally.

It is essential for success in treatment that the medical officer should feel convinced that the patient's symptoms are not organic, or are at most only in part organic. It is sometimes impossible to distinguish with certainty between hysteria and malingering; but the distinction is of no great importance if, when malingering seems possible, the statement is made in the man's hearing that "nervous" cases are cured by the treatment to be adopted, but that "skrimshankers" are not.

Whatever treatment is employed, the encouragement produced by the presence of cured patients in the same ward is most helpful. I have found that deaf-mutism rarely lasts for more than twenty-four hours after a patient's admission to my section, even if he has been in this condition for many months and many forms of treatment have been tried in vain, as there is always a cured deaf-mute present, who at once tells the new-comer by writing or by the deaf and dumb language how he was quickly cured after being unable to hear or speak for five or six or even twelve months, so that his mind is prepared for the treatment which he is told he will have on the following day.

The patient is also made to understand that there is nothing unusual about his case. The extreme interest and sympathy with which he had been surrounded accounted for the numerous cases in which hysterical symptoms had persisted for many months spent in some luxurious auxiliary hospital. He is made to realize that many others have had similar symptoms before and have rapidly recovered, and that his early recovery is regarded as a matter of course.

Hysterical symptoms being invariably due to suggestion, can invariably be cured by suggestion or simple persuasion, and to diagnose a symptom as hysterical can only be justified if the next step is to cause it to disappear.

Simple persuasion, followed, when necessary, by re-education, is all that is required to cure most cases of hysterical paralysis and abnormal gaits, whether associated or not with contractures. Massage is only of use in neglected cases, in which muscular atrophy has resulted from prolonged disuse, and then only as an adjunct to persuasion and re-education. Electricity is quite useless unless employed solely as a means of suggestion; strong faradism applied with the wire brush over paralysed muscles can be used to convince a sceptical patient that the muscles are capable of strong contraction, and the pain produced acts as a powerful means of persuasion for the fortunately rare type of man who appears to prefer to remain paralysed to recovering. On the other hand, massage and electricity employed regularly by sympathetic nurses only help to confirm the patient in the belief that he is suffering from serious paralysis.

A paraplegic man is first helped to move his legs whilst he lies in bed, and he is then made to move them without help. He is told that the movements of his legs are now so strong when he is in bed that there can be no doubt he will walk if he summons up sufficient courage to try.

Without any delay he is made to sit up in bed, then stand up and walk; both hands are held for a moment, then one hand, and then his coat is lightly held, and, finally, he is made to walk alone without a stick; in most cases the whole process takes less than five minutes.

In long-standing cases the patient generally assumes a stiff unsteady gait on first learning to walk; this only disappears as a result of re-education, the patient being made to walk, perform exercises whilst lying and sitting, and swing his legs whilst sitting on a table or holding a chair for at least a quarter of an hour three times a day. Exercise on a rowing machine or tricycle is also useful.

Some cases of long-standing hysterical paraplegia improve to a certain extent with persuasion and re-education, but then become stationary. This is generally due to the occurrence of clonic spasms, when an effort is made to move the legs on lying down or even when they are passively moved; a false ankle clonus is very easily produced, and its occurrence directly the foot touches the ground produces a permanent tremor on sitting, and a very unsteady gait on attempting to walk. We performed spinal anaesthesia on a man with this condition who had shown no improvement for many weeks. As its effects passed off we carried out passive movements of his legs, which had become flaccid for the first time, and then encouraged him to perform similar active movements, and by the evening he was walking normally. We have repeated the treatment in several similar cases; with one exception improvement followed, but not often so rapidly.

When a mute or aphonic man has been told that he will recover so convincingly that he himself feels no doubt about it, it is immaterial what form of treatment is applied so long as it has not already been tried on the patient unsuccessfully. In many cases the introduction of an intralaryngeal electrode is sufficient, but it should previously be connected with a faradic battery in case speech does not return within a few seconds, as the more powerful suggestion caused by the pain and contraction of the muscles of the throat will then succeed. In cases in which electricity has already been used, but has failed owing to being unaccompanied by sufficiently vigorous suggestion, the patient should be given ether so rapidly that he quickly becomes very excited; he almost always talks spontaneously, but an electrode may be introduced into the larynx if there is any delay. He is then made to talk continuously until he has completely recovered from the anaesthetic.

If stammering is treated the moment it develops in the course of recovery from mutism it can often be quickly cured. It is rarely a primary symptom, but often persists for long periods after mutism has disappeared spontaneously or as a result of treatment. Suggestion with the aid of electricity, etherization, or under hypnosis, occasionally produces rapid recovery, but more frequently improvement occurs very slowly as a result of re-education, lessons in breathing and talking being given regularly every day.

Hysterical fits are quite common in soldiers. They can be diagnosed from true epilepsy by inducing one by suggestion under hypnosis, if the history leaves any doubt and no fits have been observed by the physician himself. I always combine this method of diagnosis with treatment by telling the patient before, during, and after the fit that this one will be the last he will ever have. The treatment has proved most successful, as several men, who had been having numerous fits every day in spite of large doses of bromide, have had no more after their hysterical nature had been proved and their repetition contra-suggested in this way, though bromide was discontinued.

In three cases of absolute hysterical deafness seen with Captain E. A. Peters, in whom all simpler treatment had failed, we advised the patients to undergo an "operation," which we told them was quite certain to cure them. They were given enough ether to make them excited, and two small cuts were then made behind one ear; a hammer was banged on a sheet of iron during the "operation," and the moment after the incision had been made the patient jumped off the table with his hearing restored, although in one case he had been deaf for over nine months. The joy shown by the patients on their recovery whilst in the theatre and on return to the ward was so obviously genuine that there could be no possible doubt about the genuineness of the deafness. Moreover, it had been found impossible to

wake them at night by means of the loudest noises, and the auditory motor reflexes were absent in two of the cases.

Six cases of hysterical blindness I saw with Major A. W. Ormond were cured by hypnotic suggestion when all other treatment had failed.

(d) HYPERADRENALISM AND HYPERTHYROIDISM.

Strenuous action is normally rendered possible by the sympathetic nervous system, which is stimulated to great activity by the emotions of fear and anger under conditions which imperil the safety of the individual. Impulses reaching the suprarenal glands by their sympathetic nervous supply stimulate them to secrete adrenalin. It has been shown experimentally that both the injection of adrenalin and the increased secretory activity of the suprarenal glands which occurs in times of stress give rise to all the effects produced by stimulation of the sympathetic nerves. Suprarenal activity thus powerfully reinforces the direct action of the sympathetic nervous system, which enables the individual to respond to the emotions of fear and anger by strenuous action. There are no constrictor fibres to the cerebral and pulmonary arteries, and the sympathetic fibres to the coronary vessels produce dilatation instead of constriction, so that the vaso-constriction produced by adrenalin is confined to the splanchnic system; the blood pressure is thus raised, and the blood is driven to the heart, lungs, brain, and muscles from the abdominal viscera, the activity of which is simultaneously suspended by the inhibitory influence of the sympathetic nerves. At the same time, the heart is stimulated to beat more rapidly and vigorously. The skeletal muscles not only receive an increased supply of blood, but also of the sugar required for their activity, as adrenalin augments the stimulating action of the sympathetic on the production of sugar from the glycogen in the liver. The products of muscular activity, the accumulation of which leads to exhaustion, are neutralized or destroyed by adrenalin independently of any sympathetic action. The central nervous system, the heart, and the muscles of the limbs and trunk, are thus prepared for great activity. The evaporation of sweat, the secretion of which is increased, prevents the rise of temperature, which would otherwise occur with excessive muscular activity, and the deep respiration and the relaxation of the bronchioles allow more oxygen to enter the lungs and excess of carbon dioxide to escape.

Adrenalin acts very rapidly, but for a short period, as it is quickly oxidized. It is consequently of special importance when an emotion calls for sudden activity. When more prolonged activity is required, the internal secretion of the thyroid gland probably helps to maintain the activity initiated by adrenalin, as it acts after a longer latent period, and its action is more prolonged.

The physiological effects of the fury and excitement of battle enable the born soldier to perform feats of strength and endurance which may be in striking contrast to his comparatively feeble physique. But the changes which accompany fear and anger are entirely useless if the emotions are not followed by the associated instinctive activity. So fixed, however, is the primitive association of anger with fight and fear with flight, that when the natural sequels of these emotions are restrained they continue to give rise to suprarenal and thyroid activity. Thus the ceaseless fear felt by the constitutionally timid when exposed to the horrors of war results in constant over-secretion of the suprarenal and thyroid glands, the physiological results of which are not followed by the muscular activity of flight for which they are the preparation. The unexpended energy may be so extreme that the soldier is incapacitated by it. On reaching the safety of a base hospital the hyperactivity of the suprarenal and thyroid glands and the signs and symptoms to which they give rise often disappear. But they may be perpetuated by war-dreams, and in severe cases the mind is absorbed by day as well as by night by pictures of the horrors which the individual has witnessed; every sound reminds him of shells, and every movement suggests the approach of danger. The activity of the suprarenal and thyroid glands is consequently maintained, and the patient presents a picture suggestive of Graves's disease, although hyperactivity of the suprarenal glands is probably of more importance, though less easily recognized, than that of the

thyroid. The pulse is rapid, especially on the slightest exertion, and the heart may be slightly enlarged. The blood pressure of the average soldier in the front line trenches is slightly subnormal, but in these cases it is always raised, and is often still 150 mm. of mercury or more on arrival in England.

I have observed a very characteristic cutaneous reaction in these cases, which is present in no other condition. On moving the finger over the skin of the chest so lightly that in normal individuals no local reaction would occur, a pilomotor reflex is almost instantaneously produced; goose skin is obvious and occasionally the hair can actually be seen to stand on end over the area touched by the finger and for some distance on each side. After about five seconds the pilomotor reflex fades away and is at once replaced by a vaso dilator reflex; the blush, which may have a white border on each side, often lasts for several minutes. As improvement occurs the vasomotor reflex disappears, but the pilomotor reflex generally persists for a few weeks longer. The circulatory symptoms may be so prominent that the case is often diagnosed as "disordered action of the heart." The condition may then be described as the "hormonic type of soldier's heart." Excessive sweating often occurs, sometimes in paroxysms, especially over the palms of the hands and soles of the feet, and the patient loses weight. The hands and occasionally the eyelids are tremulous, and the patient is highly nervous and excitable. The eyes are often slightly prominent, and von Graefe's sign may be obtained. The thyroid gland, though over-active, is generally not obviously enlarged, but in some cases moderate enlargement is present.

Treatment.

The patient must be isolated at first from the other patients in the ward by screens, and should only see such visitors as he believes will allay rather than increase his nervous irritability. He should be protected from any chance of being reminded of what he has passed through by thoughtless conversations or illustrated papers.

Mental activity and restlessness are lessened by small doses of opium, this being the only war neurosis in which this drug can be safely employed, and also by suggestion, especially when nightmares or some special sources of worry are present. The thyroid and adrenal secretion are kept in check by belladonna. The blood pressure rapidly falls to normal and all symptoms gradually disappear. X-ray applications to the thyroid gland have been used with success in some cases, but it is impossible to regulate the destructive action of the rays with sufficient accuracy for perfect safety, and the other ductless glands are not dealt with.

(e) EXAGGERATED DEFENSIVE REFLEXES.

The "flinch reflex," which is caused by the sight or danger approaching, consists in the assumption of a crouching attitude; the arm is raised in front of the face and the eyes blink; it has the object of hiding the individual and defending him from attack. The "jump reflex" consists of a sudden movement of the limbs and trunk, and is associated with blinking of the eyes and dilatation of the pupils; it is caused by sudden sounds, and is really the preparation for the immediate activity which would be displayed if the individual obeyed his instinctive desire to save himself by flight. These responses are true defensive reflexes and have their centres in the mid-brain.

The common exaggeration of the jump reflex in soldiers suffering from certain war neuroses is not therefore correctly described as hyperacusis, for the sense of hearing may be no sharper than normal, and actual hearing need not occur at all, as the reflex occurs when they are asleep and hypnotized as well as in some cases of hysterical deafness. It is simply a part of the general exaggeration of the defensive reflexes, which is a characteristic feature of those war neuroses which are due rather to emotions such as prolonged fear than to the actual concussion of pure shell shock. In one severe case true hyperacusis was present, and Captain E. A. Peters estimated that the patient heard sixteen times more acutely than the average normal individual. It was possible to carry on a conversation with him by whispering in one corner of the ward when he was lying in the opposite corner, although men

with normal hearing who were standing half-way between in the centre of the room could not hear a word of what was whispered. The hyperacusis and exaggerated defence reflexes were quite uninfluenced by the administration of 100 grains of bromide a day.

In severe cases the patient appears to be in extreme terror; he jumps violently, and trembles from head to foot at the slightest sound; he raises his arm as if to protect his face from a blow and hides his head under the bed-clothes when anybody approaches him. After all trace of terror has disappeared as a result of suggestion under hypnosis, and the patient no longer thinks or dreams of the horrors of war, the appearance of terror may continue unabated, the intense emotions to which the patient has been subjected having led to such an increase in the excitability of the central nervous system that the exaggerated jump and flinch reflexes persist after the cause of their exaggeration has disappeared.

Treatment.

Complete physical and mental rest are essential. No visitors should be allowed, and frequent changes of nurses are most undesirable. Severe cases should be kept in bed and isolated until considerable improvement has occurred. The patient should not talk about his experiences, but should try to forget the scenes he has passed through. Nightmares and day-dreams should be treated by hypnosis. Bromides have very little effect, except in mild cases, but medinal and aspirin often helps to produce sleep. When true hyperacusis is present the ears should be plugged with wool, and in severe cases, in which this has little or no effect, large woollen pads should be tied over the ears at night or during a thunderstorm.

III.—SHELL SHOCK.

The term "shell shock" should be reserved for the condition which follows exposure to the forces generated by the explosion of powerful shells in the absence of any visible injury to the head or spine. In all cases there is an organic basis, which consists of the more or less évanescent changes in the central nervous system resulting from the concussion caused by aerial compression, to which is often added concussion of the head or spine caused by the sandbags of a falling parapet, or by the patient being blown into the air and falling heavily on to his head or back. On this organic basis hysterical or psychasthenic symptoms are often superposed.

Post-mortem examinations on men who have died without regaining consciousness after being blown up by high explosive shells in the absence of any external injury, have shown multiple punctate hæmorrhages in the white matter of the brain and the nerve cells show chromatolysis with eccentric nuclei. Mott has pointed out that if a man is buried under sandbags in a heavily shelled trench or dug-out, or if for any other reason he is confined in a small space in which the carbon monoxide produced by an explosion collects without being able to diffuse rapidly away, he will be rendered unconscious, if he is not already unconscious as a result of concussion. The continued inhalation of the gas will cause him to suffer from the effects of carbon monoxide poisoning, although he will not have realized during his period of consciousness that he was inhaling a poison, as the gas is odourless. The pathological changes produced are identical with those found in fatal cases of shell shock, so that carbon monoxide poisoning may perhaps be responsible for some of the symptoms in a small proportion of cases.

Several French observers have found that if a lumbar puncture is performed in a case of shell shock within a few hours of the onset of symptoms the cerebro-spinal fluid is generally under increased pressure, and contains albumin, blood, and slight excess of lymphocytes. If the examination is repeated in forty-eight hours the abnormalities are no longer present. This accounts for the fact that the cerebro-spinal fluid is almost invariably normal when the lumbar puncture is performed at a base hospital.

In such cases it is clear that organic changes have occurred in the central nervous system, which are, however, so slight—consisting probably of minute capillary hæmorrhages and chromatolysis of nerve cells—that they rapidly and completely disappear.

Symptoms.

Two groups of cases may be recognized. In the first the symptoms are due entirely to concussion of the brain and spinal cord; in the second hysterical manifestations are grafted on to this organic basis.

1. PURE CONCUSSION.

(a) *Cerebral Concussion.*

The symptoms of uncomplicated shell shock are identical with those of concussion in civil life. The immediate effect of a high explosive shell is to render a man unconscious. In the severest cases the patient's breathing is stertorous and he may die after an interval of a few hours or days without regaining consciousness. In the more serious of the cases in which recovery ultimately takes place the patient passes into a condition of stupor, which is indistinguishable from that already described as resulting from emotional strain without actual concussion. As a rule the patient soon recovers his memory up to the time of the explosion, and may even recollect that he heard the sound of the shell coming, but from this moment his mind is a blank. Less frequently the memory is perfect up to a certain date, such as the day of arrival at the front, but all subsequent events are forgotten; the patient appears to live over some of the forgotten events—especially those of a terrifying nature—in his dreams, but on waking he remembers nothing of them. In severe cases more or less complete retrograde amnesia may be present. Headache is a constant symptom. It is increased by the smallest mental effort, and is often worse at night, when it may prevent sleep. Lumbar puncture often shows that the pressure is raised, and the removal of cerebro-spinal fluid then relieves the headache, but rarely for longer than a few hours. It is greatly aggravated by nightmares and the recollection of horrors through which the patient has passed. For many months after the severe headache has disappeared, a heavy, full sensation may still be caused by mental concentration or excitement, and sustained attention is impossible, because of the sense of weariness it causes. Mental irritability is a common early symptom and often continues after the patient is otherwise well. He loses his temper for trivial causes and may get himself into trouble for insubordination.

One officer was greatly worried on account of seminal emissions, which had occurred three or four times every night since he was blown up by a shell a month before I saw him. They were always accompanied by war dreams, and disappeared permanently after suggestion under hypnosis on a single occasion.

(b) *Spinal Concussion.*

Spinal concussion may occur as a result of a blow on the back, but it is more often due to an explosion in which the patient is buried under earth or sandbags. The skin and muscles over the spine may be bruised, but often no sign of injury can be found. I have seen several cases in which concussion has resulted from an actual wound, in which the missile passed near the spine without actually injuring it.

Roselle and Oberthur examined a number of men suffering from spinal concussion whilst still in the trenches within a few minutes of their injury. They found that the tendon reflexes were exaggerated and the cutaneous reflexes were absent, except the plantar reflex, which was extensor; extreme hypotonus of all muscles was present.

In slight cases the hypotonus passes off in a few hours, often whilst the patient is still unconscious, the legs becoming slightly spastic with normal or exaggerated knee-jerks, and the plantar reflex is now absent or flexor. In more severe cases the muscular tone is diminished for a longer period, and an extreme degree of flaccidity may be present; the knee and ankle jerks are then weak or unobtainable; in the course of time the tone returns, the jerks become normal, and the paralysis disappears.

When, however, more profound changes have been produced in the cord the flaccidity is replaced by increasing spasticity with increased jerks, ankle-clonus, and extensor plantar reflexes. In most cases complete recovery with disappearance of all abnormal physical signs occurs, but in some cases slight spasticity with exaggerated jerks and occasionally extensor reflexes persists, the concussion having resulted in some permanent lesion of the spinal cord. In most cases the spine is tender; there may be some rigidity, and pain occurs on bending or twisting. **▲▲**

x-ray examination shows that there is no actual injury to the spine.

In many cases faeces and urine are at first passed involuntarily.* The initial incontinence does not last more than a few hours. It may then be replaced by retention for twenty-four hours, and this is sometimes followed by difficulty in micturition for two or three days, but the condition of the bladder is generally normal by the time the patient reaches England.

2. HYSTERICAL SYMPTOMS GRAFTED ON TO ORGANIC BASIS OF CEREBRAL OR SPINAL CONCUSSION.

In the confused mental condition which follows shell shock a man is abnormally suggestible, particularly if he is already exhausted owing to the stress and strain of active service. The organic paraplegia which is the result of transient structural changes in the spinal cord produced by concussion disappears with the return of the cord to its normal condition; it is then often replaced by hysterical paraplegia. Finding that he is unable to move his legs when he first regains consciousness, a man becomes convinced that he is paralysed and makes no further efforts; the paralysis thus produced by auto-suggestion can be removed by persuasion or a counter-suggestion. In the same way, when one side of the brain has been chiefly affected by the concussion, an initially organic hemiplegia merges into hysterical hemiplegia. I have watched several cases, in which all the physical signs of organic paraplegia or hemiplegia were at first present, but have gradually disappeared in the course of a few days or weeks, although the paralysis has remained, until by suggestion or persuasion it has been cured in a few minutes. Sometimes, however, some organic signs remain, and suggestion then can only produce an incomplete cure, a slightly spastic gait or some slowness and lack of accuracy in the first movements of a limb being left as the permanent result of the shell shock.

As complete or almost complete recovery from the organic symptoms occurs in the vast majority of cases, the prognosis can be regarded as good, and an attempt should be made as soon as the initial stupor has passed away to persuade the patient to walk. It is extremely difficult so long as any organic signs persist to judge to what extent the symptoms are organic in origin, but experience has shown that some physical signs of organic disease, such as an extensor plantar reflex, greatly exaggerated knee-jerks and true ankle-clonus, and unilateral absence of the abdominal reflex, may still be present when the character of the gait and its rapid improvement with persuasion and re-education show that the symptoms are almost entirely hysterical.

Apart from the hysterical manifestations which result from the perpetuation of symptoms produced by transient organic lesions of the central nervous system, others may be produced by auto-suggestion without any primary organic condition. These hysterical manifestations are very varied, and it is at first difficult to explain why one man should become blind, another deaf and dumb, and another hemiplegic under apparently identical conditions. From careful inquiry into the history of numerous cases I have come to the conclusion that the variability of the symptoms can best be explained in the following way. As a result of the various factors which give rise to shell shock all the functions of the body are in abeyance for a period which varies in different cases; the patient cannot see or hear or feel, he cannot talk, he cannot move, and his mind is a complete blank. In many cases all these lost functions gradually return in the course of a few hours, though some come back more rapidly than others; the patient is then in much the same condition as a man who has been concussed by falling on his head, with a number of symptoms, such as headache, difficulty in concentration, and lack of energy, but there is no paralysis nor loss of any of the special senses. In other cases, as consciousness returns, the patient's mind becomes fixed on some part of his body which is painful, the pain being the first impression powerful enough to attract his awakening attention; or the temporary inability to see or hear or speak, which generally remains unnoticed when consciousness first returns because of the absence of any desire to see or hear or speak, is suddenly realized owing to a special call being made on one of these functions. The patient's dawning intelligence becomes fixed upon this single missing function, and he suggests to himself that the disability will be

permanent. The fact that the other functions are missing remains unnoticed, and after a time they spontaneously return. The persistent localized loss of function is thus due to auto-suggestion leading to the perpetuation of what would otherwise be a very temporary incapacity; it can thus correctly be described as hysterical.

Less frequently the impressions received by the patient between the moment the explosion occurs and the moment when consciousness is lost give the key to the symptoms. The first thought of a man on regaining consciousness after being deafened by the noise or "struck dumb" with terror when the explosion took place may result in the suggestion of deafness or dumbness.

Treatment.

Rest in bed is required for the symptoms of shell shock which are the result of actual concussion. In civil practice it is a common event to see patients suffering from chronic headache after cerebral concussion, and chronic backache after spinal concussion, both of which might have been prevented by sufficient rest immediately after the injury. The same is true after shell shock and burial, and many men, who pass from one hospital to another for many months receiving all sorts of expensive treatment with little or no benefit, could have been rapidly cured by simple rest immediately after the injury. On the other hand, the rest must not be too prolonged, and it requires considerable experience to judge the right moment when such patients should be allowed to get up. If kept in bed too long, they are very liable to lose their power of standing and walking, as the care taken to keep them at rest may give them the idea that they are severely injured, and hysterical astasia-abasia or paraplegia develops. In order to prevent this, the patient should be made to get up to go to the lavatory and to have a bath from the first day, except when severe stupor is present, in which case he should get up as soon as it has sufficiently diminished. When the patient no longer complains of pain in the head or back, he should be encouraged to take exercise, the amount of which should be steadily increased. Massage often aggravates the pain, and it tends to increase the tendency to introspection.

The associated hysterical symptoms should be treated in the manner already described.

AN INVESTIGATION OF TRENCH NEPHRITIS BY MEANS OF PHENOLSULPHONEPHTHALEIN.

BY

A. G. AULD, M.D., M.R.C.P.,

VISITING PHYSICIAN, MILE END MILITARY HOSPITAL, LONDON.

It is not always a very easy task to exhibit faithfully in tablet form work which has extended over twenty months. Nevertheless, the attempt has been made in this paper without, if possible, rendering the picture incomplete. For many facilities in connexion with the investigation I have to thank the officer in charge, Lieut.-Colonel J. Harley Brooks, M.D., R.A.M.C.

To American workers we are specially indebted for the advances in biochemistry relating to the renal functions which have been a feature of the past six or seven years. Folin and Denis, and Van Slyke, in particular, have done pioneer work, and produced indispensable tests for the various non-protein waste products of the blood and urine. A voluminous literature has already accumulated round this subject, which is steadily being pursued with excellent promise. One of the most fruitful means of investigation was undoubtedly supplied by the introduction of phenolsulphonephthalein as an index of renal function by Rowntree and Geraghty in 1910.¹

The technique of the test may be studied in the original; suffice it to say here that it consists in the subcutaneous injection of an alkaline solution of 6 mg. phthalein after preparation of the patient. The urine is collected after one hour and after two hours. A few drops of 25 per cent. NaHO solution is added to it, and the resulting pink colour, after dilution of all the urine with water up to a litre, or the equivalent of this dilution of a small quantity, is read off in the colorimeter, or against tubes containing

standard colour solutions of the dye. An excretion of 50 per cent. of the amount of dye injected may be set down as the normal average in one hour, and 25 per cent. in the second hour. Both the hourly and two-hourly percentages are usually taken, but after repeated trials I have found that ordinarily the first hour's percentage is sufficient. Indeed, if anything, it is the more searching test, as in the case of defective kidneys the second hour's excretion is often higher than that of the first. It is essentially the slowness of the elimination which characterizes renal defect.

Rowntree and Geraghty consider the phthalein test superior to methylene blue, indigo-carmin, rosaniline, and phloridzin, owing to (1) ease of application, (2) rapidity of action, and (3) reliability. These investigators also found the calculation of the urea output, total nitrogen, total solids, and quantity of the urine passed to be "of no value whatever as indicating the true renal activity." As regards other tests for renal function, besides being much more difficult, and tedious of execution, they are open to certain fallacies. The lactose test of Schlager, and the diastase test of Wohlgemuth have been chiefly used. As regards the first, it sometimes contravenes a result uniformly given by other tests. As regards the latter, recent work of McClure and Pratt² has shown enormous variation both in normal and pathological cases. Wohlgemuth placed the maximum normal limit at 64 diastatic units, but certain of the cases investigated showed anything up to 400 units. The dietary test introduced by Hedinger and Schlager in 1914, and its modification by Mosenthal, is no doubt of high value, if very tedious. Cases of severe anaemia, however, respond to it in the same manner as advanced nephritis.

The Non-protein Nitrogen of the Blood.

Renal efficiency means above all else the power of the kidneys to eliminate adequately the non-protein or in-coagulable nitrogenous bodies—urea, uric acid, creatinin, etc.—which accumulate in the blood not only under ordinary conditions, but also under exceptional circumstances of diet, exercise, etc. Accordingly, a great many investigations have been made with the view of estimating the various movements, so to speak, of these substances, and the significance attaching to them in the various conditions of disease. In health great fluctuations are found in the urea concentration of the blood, diet being an influential factor. But in renal disease also, as shown by Folin, Widal and Javal, and others, the urea of the blood may be made to fluctuate at will by varying the protein intake. A reasonable upper normal limit for urea is 30-40 mg. per 100 c.cm. of blood, for uric acid about 3 mg., and for creatinin about 2.5 mg. For the total non-protein nitrogen about 30 mg. per 100 c.cm. of blood is a reasonable upper normal limit, the urea nitrogen being about half the total, or 15 mg. In acute or far-advanced cases of nephritis the urea of the blood may mount up to hundreds of milligrams per 100 c.cm., but in the earlier chronic stages the figures may easily approximate to normal, and continue so indefinitely under appropriate diet. No information as to the state of the kidneys would be obtained in such cases from an examination of the blood alone, yet renal deficiency would certainly be indicated by the phthalein test. A notable advance was, however, made by Ambard, who arrived at certain laws as to the ratio between the concentration of urea in the blood and the rate of its excretion by the kidney per unit of time. He believed he had found that normally a constant relationship exists betwixt these two factors—the constant or coefficient of Ambard. This law has been subjected to very searching tests, one of the most recent being by Addis and Watanabe,³ who found variations in the constant in health under conditions of increased urea derived either from food or from disintegration of tissue protein, or preformed from the alimentary tract. Apart from this, however, in renal disease there is a relative increase in the urea concentration in the blood and a relative decrease in the rate of excretion. There is a general consensus of opinion that in nephritis Ambard's coefficient and the phthalein test give fairly parallel results, and of the two the phthalein is the more reliable.

Phenolsulphonephthalein has also been used in this investigation as an indicator for the hydrogen ion concentration of the blood and the alveolar carbon dioxide tension after the method of Sørensen, using acid and

alkaline phosphate mixtures as standard solutions. The phthalein is specially adapted for this purpose, as, according to Levy, Rowntree and Marriott, it is the best indicator for minute differences in the H ion concentration between $10^{-6.4}$ and $10^{-8.4}$ (passing through neutrality). Full instructions for carrying out the tests have been given by Marriott.⁴

In the case of the blood it is necessary to indicate the H ion concentration in terms of the reserve alkalinity of the serum after driving off the CO_2 by a current of air. This is expressed (after the notation of Sørensen) as R p H. The serum is dialyzed through a celloidin sac into a saline solution of the indicator, the CO_2 is driven off, and the colour compared with those of standard tubes. The process requires to be done most carefully, owing to the great delicacy of the reagents.⁵ Normally, the reserve alkalinity is R p H 8.5 or very nearly. I examined eight cases in the earlier chronic stage of the disease, and obtained values from R p H 8 to normal. On the other hand, the estimation of the alveolar CO_2 is very easily performed, and for routine ward work most handy. The air is collected by the Plesch method, the respirations into the bag (containing 1,000 c.cm. air) occupying twenty-five seconds. The expired air is then bubbled through a standard alkaline phthalein solution, and when the change of colour is complete, the tube is compared with a graded series of standard phosphate-phthalein tubes.[†] The entire test may be completed within five minutes, but the patient must first be taught to breathe properly.

In the nephritis cases no low tensions were found except in a few presenting either pulmonary or circulatory disturbance. Thus a case with cardiac dilatation (right sided) gave a reading of 30 mm. Hg (the normal being 40-45). But little evidence of acidosis is forthcoming from the renal condition in the post-acute stages.

General Results of the Phthalein Test.

The cases herein referred to were young soldiers discharged from hospitals abroad after the acute symptoms had subsided. Acute cases occurring at home, either in the young or middle aged, are not included. As a matter of fact, the test is useless in acute cases. The number of cases has been large, an entire ward being utilized in connexion with this investigation. The complete results are based on 42 selected cases. The routine consisted in making the test soon after the patient's admission, and repeating it at intervals of about three weeks. Concomitantly the blood pressure was recorded. The examination of the urinary sediment, tube casts, blood cells, etc., was conducted by the pathologist, Dr. Rowlands.

In what may be termed the second state of trench nephritis the urine is usually abundant, often considerably in excess of the normal, with a rather low specific gravity, though in some the specific gravity is normal. Albumin may be present in high percentage or but slight. At first blood is very frequently present, but it generally disappears a long time before the albuminuria. Tube casts are almost constantly found, generally of the granular or hyaline varieties. As recovery proceeds, the quantity of urine diminishes. Perhaps the most striking thing about the phthalein test is that it bears no relation whatever to the quantity of albumin or the presence of tube casts. A patient with slight albuminuria *minus* casts may give only an excretion of 20 per cent. in the hour, whereas a case in which the urine is loaded with albumin and containing numerous casts may give a 50 per cent. excretion. At first this was a very puzzling phenomenon, but the progress of the case always justified the verdict of the phthalein, given thus early, as to the ultimate result. As soon, therefore, as such patients are admitted to hospital we can make a prognosis from this test without reference to any other factor in the case. It is needless to expatiate on the value of this.

Certain observers—Pepper and Austin, Baetjer, Sellards—have alleged that cases of severe parenchymatous nephritis are occasionally encountered in which there is hyper-permeability on the part of the kidney to the substances used as functional tests, including phthalein. Pepper and Austin give two such cases having phthalein excretions of 50 per cent. and 46 per cent. respectively in

* These, with the celloidin tubes, were made by Martindale.

† These were prepared by Baird and Tallock.

one hour. Deficient chloride elimination was observed also. Sellards has one case; Baetjer has four (also with deficient chloride elimination) in which he also noted the fluid balance, the elimination of lactose and potassium iodide, and the percentage of rest nitrogen in the blood. Baetjer adds, however, that a high excretion of phthalein may justify a good prognosis in these, as "none of them have yet come to autopsy."⁶ A very comprehensive study in relation to this point was made by Thayer and Snowden,⁶ who recorded the complete results in 54 cases of chronic nephritis right up to the necropsy, and declared that in not a single instance did they fail to find a material diminution of the phthalein. The progressive diminution of the phthalein excretion with the advance of the disease was definite and striking. They observed, however, that cardiac disease with chronic passive congestion often causes a considerable reduction of the phthalein output. This point is important. I have found a reduced phthalein elimination in cases presenting want of oxygen, howsoever induced, or in which the alveolar carbon dioxide tension was low. Kendall,⁷ in a suggestive paper, records experiments which seem to show that oxygen protects the dye, and that it is destroyed by the reducing substances of the body. So far as trench nephritis is concerned, high excretion of the dye has never been encountered in cases which did badly. On the contrary, they all made good recoveries. The elimination of chlorides and sulphates was normal in all such cases examined.

The cases in the second month of the disease showed phthalein elimination varying from 15 to 50 per cent. or over in one hour. Needless to say, the early high percentage cases do well, and some, though by no means all, also lose their albumin quickly. For the others, which form the great majority, the third month is rather critical. It may be best to summarize the matter, and indicate a classification which is the outcome of long-continued observation of the cases.

1. If, within three months from the onset of the disease, the phthalein excretion rises to 40 per cent. or over in one hour, recovery will be good, even should albuminuria continue for another two months or possibly longer. For part of this time casts may also be present.

2. If, at the end of the third month, the phthalein excretion be under 30 per cent. in one hour, notwithstanding a slight degree of albuminuria, or with intermittent albuminuria, recovery will be protracted, and in some of the cases unsatisfactory.

3. If, at the end of four months, the phthalein excretion reaches 40 per cent. or over, ultimate recovery is the rule, even should the albuminuria last for several months longer.

4. If the excretion remains persistently low (15 to 30 per cent.) up to the fourth or fifth month, the prognosis is unfavourable without reference to the presence or degree of albuminuria. Several such cases which reported themselves after eight to nine months still presented a low index of elimination and slight albuminuria. As to the final issue, it is difficult to say, but the fact that they all had either normal blood pressures, or slightly over, seems to presage in some of these a favourable result.

As regards the distribution of the cases, if we include in Class 1 those showing high elimination in the second month, a total of about 50 per cent. would be represented in this class. The cases in Class 2 proceed either to Class 3 or Class 4, between which the remaining 50 per cent. were fairly evenly distributed, if anything a slightly higher percentage being in Class 3.

A good many cases admitted were relapses after being sent back to active service from other centres. No doubt in these the albuminuria had disappeared at the time, but it is doubtful if the phthalein test (had it been made) would have been satisfactory. Even had it been, one is compelled to doubt if a return to active service is in any case warrantable. It is very probable that in a goodly percentage of the cases some antecedent kidney disability, or a tendency thereto, existed.

The phthalein test also serves as a very good guide to dieting. An excretion under 30 per cent. indicates a milk and vegetable diet; 30 to 35, the addition of fish or chicken; and over 35, ordinary diet with extra milk, provided the albuminuria is moderate and not increased by the diet, and blood is absent. All cases appear to derive benefit from an iron mixture.

Considerations as to the Pathology of the Disease.

What may be termed the clinical impression given by trench nephritis differs materially from that of ordinary parenchymatous nephritis. The subjective feeling of well-being, and the absence of the symptoms of ill health in the

vast majority, are characteristic. The disease may present two very puzzling features. One is the intermittence of the albuminuria which occurs in a few cases, even where the albuminuria is of a high grade. Complete absence of albumin may be recorded one day, and on the next or a few days thereafter perhaps as much as 1 to 1.5 per cent. may be present. Care, of course, must be taken lest an alkaline urine be present which fails to react with heat. The other curious condition is a persistent high degree of haematuria without albumin latterly (except such as is due to the blood). On these conditions speculation is perhaps better avoided. The long persistence of a high grade of albuminuria, with casts in some cases, might seem to create a need for revision of our ideas as to their significance. Again, except in the early stages, the blood pressure is nearly always within normal limits (110 to 135 mm. Hg), and, as we have seen, the kidneys may perform their functions perfectly as soon as the acute stage is over. The disease is doubtless due to an infection. Certain microscopical findings by Dunn and McNe⁸ can hardly be regarded in an etiological sense. I venture to suggest a comparison with acute pneumonia. Just as an entire lung may be involved in the acute stage, so, doubtless, the entire kidney is at first inflamed. When resolution occurs, a district or districts of kidney fail, just as may occur in a section of lung, which continues in the state of delayed resolution—that is, an epithelial overgrowth and desquamation. Such a lung may, of course, be perfectly competent to carry on normal respiration even under average conditions of exercise, and recovery of the damaged area may ultimately be complete. This view of the kidney lesion explains the presence of albumin and tube casts alongside a normal functioning power and a normal blood pressure. As regards the abundant secretion of urine, this would seem to depend on vaso-dilatation of the renal vessels, due to metabolic products.

THE OCCURRENCE OF SPIROCHAETES IN THE URINE.

BY

JAMES L. STODDARD, 1st LIEUT., M.O.R.C., U.S.A.,
U.S.A. BASE HOSPITAL No. 5.

A WIDESPREAD interest in the increasingly numerous group of diseases known to be caused by spirochaetes, and the consequent desire for a rapid and sure means of diagnosis, have brought forward the possibility of recognizing such cases by finding the spirochaetes in the urine.

I.—INTRODUCTORY.

That spirochaetes may actually be excreted by the kidney in diseases of spirochaetal origin is a fact resting on the reliable experimental evidence of the workers on spirochaetosis icterohaemorrhagica. Their animal experiments have demonstrated that spirochaetes occur in the urine which have the same pathogenic effect on guinea-pigs as the organisms found in the blood. Obviously a similar excretion may occur in other diseases, and thus afford an easy means of diagnosis.

Certain observations made recently at this hospital, however, show a source of error in a procedure of this kind. It was found, in brief, that:

1. Spirochaetes are not uncommon organisms in the urethra of men without history or symptoms of relapsing fever.
2. Many different varieties are found.
3. Some of the varieties seen are morphologically closely similar to pathogenic varieties.
4. The spirochaetes occur so definitely within the urethra that they are an obvious source of contamination in uncatheterized specimens of urine.
5. They are a sufficiently dangerous source of error, even in catheterized specimens, to deserve attention in careful work.
6. It is possible that a staining reaction or some other morphological character may be discovered to differentiate microscopically the common and harmless from the patho-

genic spirochaetes. Since the pathogenic spirochaetes are still in the process of discovery, such methods are not universally applicable.

The facts summarized above are possibly known to a few workers, but they are not to be found in the publications at our disposal. They are new to us, and probably to a majority of those who are likely to make use of them. That a source of error in diagnosis may be pointed out, and possibly time saved for prospective workers in these diseases, the observations made are given herewith.

II.—FREQUENCY.

The work was initiated by the finding of spirochaetes in centrifugized specimens of the urine of a nephritic patient with relapsing fever. The urine was divided into two portions, and the sediment of the first portion passed found to contain ten to twenty times as many spirochaetes as the later portion passed. The obvious intraurethral or periurethral source was investigated by films made with a platinum loop, and spirochaetes of the same variety found in great numbers. It seemed probable that such spirochaetes were a common saprophytic organism rather than a localized evidence of a general spirochaetosis. Consequently other patients with and without relapsing fever were investigated similarly. Spirochaetes were found in the urine and in urethral smears from five out of fourteen men. In only one case were spirochaetes found locally, but not in the urine. That the spirochaetes do not have their ultimate origin in the urine seemed probable because by passing the urine in successive portions a part toward the last could be obtained in which no spirochaetes could be found. Such methods cannot be depended upon, however, to eliminate the intraurethral parasites.

When it was evident that spirochaetes of intraurethral origin could frequently be found in the urine, a study was made of 100 men without history or symptoms of any fever of a relapsing type. Fifty of these, given below in Series I, were hospital patients with miscellaneous medical and surgical conditions; many of them were gassed cases. They were selected entirely haphazard. The other fifty, called Series II, consisted of U.S.A. men who came to France from America in early June or the latter part of July.

In each case films were made with a platinum loop from the distal one-third inch of the urethra and from the region about the urethral orifice. In making the urethral smears as a rule the meatus was parted and the loop introduced with as little contact with the orifice as possible. In several cases the anatomical conditions were such that contamination from extraurethral sources undoubtedly occurred, and in other cases faults in technique may have been present. Consequently no rigid separation of sources is possible. The occurrence in several cases of spirochaetes in the urethral but not in the other smears is evidence of their intraurethral origin, in these particular instances at least. In any case they are an evident danger in urine sediment examinations. Notes were made of the presence or absence of spirochaetes, of the morphology, and of the approximate numbers.

In the following summary of the figures, each series is considered separately, then the 100 men as a whole. The percentage occurrence in urethral films is given first, for the urethra is the most definite source of contamination. In a certain additional number of cases spirochaetes were found near but not in the urethra. It is evident that these also might get into the urethra or prove a contamination in other ways. Figures are therefore given for the total incidence of spirochaetes either in or near the urethra.

The spirochaetes similar in type to those found in the urine of patients with "trench fever" or to Noguchi's description of *Spirochaeta icterohaemorrhagiae* are grouped with other spirochaetes obviously not similar to *S. refringens*. Figures are then given for all spirochaetes, including *S. refringens*. The latter figure is not as significant, for the *refringens* type is so different from the others as to cause little confusion.

In all figures, cases where only a few doubtful organisms were found are excluded.

Series I.—In this first series, consisting of 50 hospital patients, spirochaetes (excluding the *refringens* type) were found in 46 per cent. of the urethral films. If *S. refringens* is included, the total incidence of all kinds of spirochaetes amounts to 56 per cent.

Series II.—In the second series, of fifty well U.S.A. men, intraurethral spirochaetes (excluding *S. refringens*) occurred in 20 per cent. of the cases. The total incidence of all spirochaetes, including *S. refringens*, was 22 per cent.

It is our belief that the smaller percentage in the U.S.A. men is due to the better health and hygiene of the subjects. It is very probable that saprophytic organisms increase on these as on other mucous surfaces in conditions of low vigour (or hygiene). That this is the explanation here is suggested by the correspondingly smaller percentage of occurrence of the *refringens* types.

Since these differences are probably not of great significance, it is of interest to average the figures of the two series to get the incidence in the whole series of 100 men. When this is done it is found that spirochaetes of all types but *S. refringens* occur in 33 per cent. of the cases. Including *S. refringens*, spirochaetes are found in 44 per cent. If the figures for the spirochaetes present near but not in the urethra are added, the percentage of spirochaetes in either one or the other situation becomes 38 per cent. If *S. refringens* is included, the incidence is 46 per cent.

In a large proportion of cases the spirochaetes were present in the film in considerable numbers.

The comparative figures give no conclusive proof as to the real source of the spirochaetes—that is, whether in or near the urethra. They occurred, however, more frequently in the urethra by 50 per cent.

III.—MORPHOLOGY.

In regard to the morphology of the spirochaetes, studies were made principally with the tannic acid carbol-fuchsin method, but the Fontana, the India-ink, Giemsa, and the Leishman and Wright modifications of the Romanowsky methods were tested. As a rule, the stain with carbol-fuchsin was definite, but some slender spirochaetes were found which stained with difficulty. The Fontana stain was usually definite and clear. Loeffler's methylene-blue stained not at all, or very faintly. Carbol-fuchsin, without previous mordant, heated as for tubercle bacillus (but not decolorized), stained moderately well, but less satisfactorily than the mordanted stain. Flagella were not made out, although there was frequently extremely fine tapering of the extremities.

No noticeable difference could be made out between the spirochaetes found in the urine of patients with trench fever and those found in the urethral smears of other individuals.

The smears from the periurethral region were more apt to contain a greater proportion of spirochaetes of the *refringens* type, while slender, closely-coiled spirochaetes were perhaps more apt to be predominant in the urethral smears.

It was soon evident that many different varieties exist. It is not proposed to make an exhaustive study of the different kinds, but merely to point out the limits of variation found, and to describe a few common varieties.

Length.—From $3\frac{1}{2}$ to 22μ . The most common length is $6\frac{1}{2}$ to 9μ , but 11μ is not uncommon.

Spirals.—Closely coiled, rather flat to moderately deep spirals are most common. The organisms may be moderately thick or extremely slender. The length of the spiral is $\frac{1}{2}$ to 1μ . Spirals also occur flatter and longer, averaging $1\frac{1}{2}$ to $3\frac{1}{2}\mu$, but occurring up to 4μ . A frequent type has a spiral of $\frac{3}{4}\mu$ in an organism $7\frac{1}{2}\mu$ long—that is, about 11 turns in $7\frac{1}{2}\mu$. In some cases the spirals were exceedingly close and fine, and almost impossible to count.

Ends.—Often taper, but may be blunt; often end in a hook, such as is described for the spirochaete of infectious jaundice.

Regularity of Spirals.—Very often the spirals are irregular. Flat or close coils may be present in the mid part, while deeper coils may be distinct near the ends. In portions, especially toward the middle, coils may be absent. There may be deep narrow, or deep wide spirals, or flat narrow and flat wide, intermingled in various ways in one organism.

Flexibility.—Almost all the organisms seen were evidently quite flexible, being seen in U or S or other contortions.

Capsule.—In a few, especially some very fine and closely coiled spirochaetes, there is a stain of substance by the carbol-fuchsin method, which lies about the organism in such a way as to simulate a capsule. It seems more probable, however, that it is an artefact.

In one film many different varieties are often present, including frequently organisms similar to the description of *Spirochaeta icterohaemorrhagiae*.

IV.—SUMMARY.

A series of 100 men without history or symptoms of relapsing fever showed intra-urethral spirochaetes in 33 per

cent. of the cases. If spirochaetes of the *refringens* type are included, the incidence rises to 44 per cent.

The spirochaetes occurred in about 1 in 2½ men sick of miscellaneous medical and surgical conditions, and in 1 in 5 of healthy men. This difference is probably to be ascribed to differences in hygiene, and to the variations in amount of flora of mucous surfaces familiar in other regions, in conditions of varying vigour.

The variety of organisms makes it improbable that the mere finding of spirochaetes in the urine can have any diagnostic value in relation to the relapsing fevers until definite morphological or other differences are established between the various normal and pathogenic varieties.

I wish to express my thanks to Lieut.-Colonel R. U. Patterson, M.C., U.S.A., for his aid in enabling me to get a complete series, and to Major R. I. Lee, M.O.R.C., U.S.A., for his suggestions.

SPIROCHAETES OCCURRING IN THE URINE OF CASES OF "PYREXIA OF UNKNOWN ORIGIN."

(Preliminary Note.)

By S. W. PATTERSON, M.D., MAJOR R.A.M.C.(T.C.),
BEIT MEMORIAL RESEARCH FELLOW.

DURING the past few months I have examined the urine of cases of P.U.O. (pyrexia of unknown origin) for spirochaetes, using a modification of Renaux and Wilmaers's technique.¹ The results are so suggestive that I venture in this preliminary note to call attention to the necessity for a systematic examination of the urine in certain clinical types of P.U.O. which may ultimately turn out to have a common etiological origin.

Since in March, 1917, Garnier and Reilly² suggested that in certain cases of icterohaemorrhagic spirochaetosis the chief incidence of the disease may be upon the kidney, I have examined a number of cases of trench nephritis and found a spirochaete in a fairly large proportion. Further, in what I regard as a definite clinical type of P.U.O. (appendicular, or abdominal—described below), which is probably a mild form of icterohaemorrhagic spirochaetosis, I have found a spirochaete almost constantly present in the urine. Again, in the relapsing type of P.U.O. (trench fever) a spirochaete can frequently be found in the urine during and immediately after the exacerbations of temperature.

Methods.

The method I have been using is as follows:

At first the specimens of urine were obtained in the ordinary way, and brought to the laboratory in clean

bottles; but later precautions were taken to try to avoid contamination of the samples. After drawing back the foreskin, the prepuce and meatus were swabbed with a 1 in 1,000 mercury perchloride solution; the patient then passed urine, and a sample towards the end of the act of micturition was caught in a large sterile test-tube. The urine was centrifuged and at first, after pouring off the supernatant fluid, the deposit was washed with sterile water and recentrifuged. Control experiments showed, however, that the spirochaetes seemed to be of comparatively low specific gravity, requiring, therefore, prolonged centrifuging (ten minutes at least, and the longer the spinning is kept up the greater the number found), and care not to remove the lowest layer of supernatant urine before recentrifuging. So it was easier, once one learnt the morphology of the organism, to pick it out in greater quantity even amongst a certain amount of debris, rather than to hunt for isolated spirochaetes on a comparatively clean slide; and the deposit was not washed.

Dark-ground illumination not being available, the following methods of dealing with the deposit were adopted:

1. Indian Ink.

Some of the deposit was mixed intimately with a drop of "Chin-Chin" liquid pearl ink (Watson) on a clean slide, and a film made by drawing along the slide a small piece of cigarette paper wetted in the drop. The film so made soon dried and could be examined directly with the oil-immersion lens. Spirochaetes, if numerous, showed up readily by this method, but the debris of the urinary deposit sometimes caused confusion and difficulty. This method, however, probably shows the spirochaetes in a more natural condition than when mordants and dyes are used.

- I. Spirochaetes of Type 1, abdominal P.U.O.
II. Type 2, relapsing P.U.O.
III. Spirillar form from urethra.

2. Tannic Acid and Carbol-Fuchsin (Renaux and A. Wilmaers).

Films are made of the deposit and fixed for ten minutes in absolute alcohol; then covered with 5 per cent. tannic acid solution and warmed till steaming; then well washed with distilled water, and, without drying, stained with carbol-fuchsin, steaming for half a minute, washed, dried, and examined. This is a very simple and rapid method, but does not give such a clear-cut picture as silver nitrate.

3. Tannic Acid and Silver Nitrate (Fontana).

The films are fixed with repeated washes of fixing fluid (acetic acid 1 c.cm., formalin 20 c.cm., aq. dest. 100 c.cm.), then washed well with distilled water; flooded with mordant (tannic acid 5 grams in 100 c.cm. carbolic acid solution 1 per cent.) and warmed for thirty seconds; then well washed with changes of warm distilled water, flooded with 1 per cent. silver nitrate, and warmed gently for half a minute, washed and mounted in balsam.

Spirochaetes.

The spirochaetes have the following characters:

They are about one to one and a half times the diameter of a red blood corpuscle, and are very thin, the ends tapering.

They show five to eight more or less regular turns, and may be straight, bowed, or lying in a semicircle.

The spirals are not so fine as in *Spirochaeta pallida*, nor so coarse as in the spirochaete of Obermeier.

The organisms are very resistant to staining, being uncoloured by Leishman, Romanowsky, or Giemsa's stains, and requiring a mordant method, but may be demonstrated by Indian ink methods.

They occur in the urine, often abundantly, during and immediately after the rise of temperature, but in the intervals may be so scarce as to be practically absent.

Like McNee³ and others, I have been unable to find any organism by direct examination of the blood of these patients, and I have not had an opportunity of determining *post mortem* at what part of the urinary tract the spirochaetes originate.

Results.

The following are the cases in which I have found spirochaetes in the urine:

Trench nephritis...	3 cases.
Pyelonephritis, with abscesses of lungs...	1 case.
Relapsing P.U.O....	15 cases.
Myalgia following P.U.O....	1 case.
N.Y.D. appendicitis...	5 cases.

Whether in these different cases we are dealing with the same spirochaete I am unable to state at present.

Clinical Aspect.

These observations suggest that we may be able to bring into line at least two clinical types of "P.U.O." (pyrexia of unknown origin).

1. A disease with acute onset with chills and vomiting, pain in the abdomen, usually more marked in the right upper quadrant, with continued fever for several days, often with enlargement of the spleen and herpes of the lips. The pulse-rate is not increased, and is usually slowed to 50 or 60 beats a minute in convalescence. There is a leucocytosis of 12,000 to 25,000 with relative increase in the large mononuclears. The cases, if an attempt is made at diagnosis, come to the base as "appendicitis," or "N.Y.D. abdominal"—the initials "N.Y.D." standing for "not yet diagnosed." I recognize that these are the cases which presented nothing but abnormal temperature, malaise, and slow pulse, and were evacuated to England. In three such cases last year I remember a note coming from Captain Stokes⁴ to the effect that the guinea-pigs into which the blood of the patients had been injected had died on the ninth or tenth day with signs of spirochaetosis. In his published cases he notes that the urines of the patients were examined with negative results. In these cases I now find spirochaetes almost constantly in the urine. French authors have suggested that cases of icterohaemorrhagic spirochaetosis may have almost their whole incidence upon the kidney, and so one finds spirochaetes in cases which cannot be distinguished from acute (trench) nephritis, except perhaps by the long continuance of much albumin and kidney debris in the urine.

2. The relapsing type of P.U.O. (trench fever) with the characteristic periodic rises of temperature, myalgic and periosteal pains, and leucocytosis with or without enlargement of the spleen, in which an improving technique has enabled me more and more frequently to find a spirochaete in the urine during and immediately after the exacerbations of temperature.

I wish to thank Lieut.-Colonel C. J. Martin, A.A.M.C., for his advice and interest in this work, which is being continued.

A FEAST of flowers is held annually in various cities in Spain for the purpose of raising funds for the campaign against tuberculosis. This year the sum of £5,640 was collected in this way in Madrid.

ACCORDING to official statistics recently published, the birth and death rates in Sweden during 1916 were the lowest ever recorded for that country. The birth-rate was 21.14 and the death-rate 13.55 per 1,000.

THE late Privy Councillor Dr. Albert Neisser, Professor of Skin Diseases and Syphilis in the University of Breslau, left his estate, valued at nearly £80,000, to the city of Breslau. He directed that his villa with its collections should be maintained as a museum for contemporary works of art, and that the rooms should be used by the municipality for high class concerts.

ACUTE SYPHILITIC MENINGITIS.

BY

S. A. KINNIER WILSON, M.D., B.Sc., F.R.C.P.,

ASSISTANT PHYSICIAN, WESTMINSTER AND NATIONAL HOSPITALS;
NEUROLOGIST, FULHAM MILITARY HOSPITAL, NAPSBURY
WAR HOSPITAL, ETC.;

AND

A. CHARLES E. GRAY, M.D., CAPTAIN R.A.M.C.,

OFFICER IN CHARGE OF THE MEDICAL DIVISION, FULHAM
MILITARY HOSPITAL.

THE invasion of the central nervous system by the organism and toxin of syphilis leads to pathological changes curiously diverse in their clinical manifestations. To take the cord only, they may range topographically from the lightning pains of a dorsal root ganglion infection, the ataxia of a dorsal column atrophy, the spastic paraplegia of a lateral sclerosis, to the pure amyotrophy of involvement of the ventral cornua. Again, from the standpoint of the time factor, they may include on the one hand an absolutely acute meningitis within a few weeks or months of infection, or on the other a chronic parenchymatous degeneration years, sometimes many years, after the original invasion.

The fact that the majority of syphilitic nervous affections are generally conceived of as running a semichronic if not actually chronic course may have thrown somewhat into the background the idea of a syphilitic infection of the meninges as acute, as abrupt, and as serious as that of any other toxic-infective condition. It is no doubt better recognized than formerly that meningeal irritation is of common occurrence in the secondary period of syphilis in the shape of rachialgia, paraesthesiae in the limbs, muscular tiredness and weakness, and increased activity of the cutaneous and deep reflexes, possibly also some slight irritability of the bladder. There may also, however, develop an actual acute meningitis, a clinical entity due appreciation of which is of prime importance from a therapeutic point of view. So well established may be the usual symptoms and signs of acute meningitis that its distinction from acute tuberculous or acute cerebro-spinal meningitis becomes a matter of considerable clinical and pathological interest.

Acute syphilitic meningitis may be regarded as appearing under three phases or at three periods in the course of syphilis.

1. It may occur as an acute exacerbation in cases of congenital syphilis.

2. It may develop during the secondary period, either with or very soon after the cutaneous exanthem, or even at a preroseolar stage.

3. It may be an episode in the tertiary stage, arising in the course of a chronic gummatous syphilis, long after infection, and sometimes when the lesions in the nervous system have appeared to be latent or quiescent.

In the first and third of these the meningeal syndrome occurs along with other symptoms or signs of syphilis, whereas in the second the clinician may be faced with the picture of an acute meningitis *per se*, and he must depend for his diagnosis on the history, or an examination of the cerebro-spinal fluid, or on certain variations in the clinical symptom-complex.

The purpose of this communication is to direct attention to the occurrence shortly after infection of this acute syphilitic meningitis by itself, as an acute fever, and to describe a striking instance which has come under our observation, in which differential diagnosis presented problems of some practical importance, and in which a complete cure resulted by means of intraspinal injections of mercurialized serum.

Hitherto most of the work that has been done on this subject we owe to the French school of neurology.

Boidin and Weill¹ have recorded the case of a youth aged 18 who developed a chancre in the middle of June; on July 15th he began to suffer from headache, and by August 5th an acute meningitis made its appearance, with headache, vomiting, rigidity of the neck, Kernig's sign, slight rise of temperature, and the attitude *en chien de fusil*. Only seven days later, on August 12th, did the roseolar eruption make its appearance. Recovery followed under treatment.

Laubry and Giroux² have published the case of a young woman of 24, with no history of syphilis, who suddenly developed violent headache, tinnitus, nausea and vomiting.

This was followed by contracture of the neck and trunk muscles, and diplopia. Kernig's sign was present. The spinal fluid on lumbar puncture showed a marked lymphocytosis, and under injections of mercury recovery ensued.

Ballet and Barbé's³ case was that of a female aged 21, who developed severe headaches, stiffness in the neck and mild delirium while the roseola was still present. Kernig's sign was obtained. In the spinal fluid was an enormous lymphocytosis. With three months' steady treatment improvement set in, but a subsequent relapse ended fatally. Generalized syphilitic meningitis was found at the *post-mortem* examination.

In a case recorded by Audry and Lavau⁴ the patient was a man of 25, in whom a chancre had appeared one month previously. There was a sudden onset of violent headache and vomiting, with neck rigidity and Kernig's sign. In the spinal fluid was a pronounced lymphocytosis. The symptoms subsided in a fortnight.

Achard and Desbouis's⁵ case concerned a female of 20, who two months previously had developed a vulvar chancre. This was only discovered subsequently, for the first symptoms were those of acute meningitis, diagnosed as tuberculous; lumbar puncture, however, and a more careful history, revealed the true nature of the condition, which rapidly improved under injections of mercury binioidide.

In a different group is the case reported by Jeanselme,⁶ where a female of 22, who had had syphilis three years previously, suddenly developed all the symptoms of acute meningitis, with violent headaches, delirium, generalized rigidity, strabismus, and the presence of Kernig's sign. The spinal fluid was remarkable for an enormous lymphocytosis. In spite of urgent antisymphilitic treatment, death followed.

Apart from such fulminant cases a large number have been reported where the symptoms of meningitis, though unmistakable, were not so severe or so widespread. Thus Ellis⁷ has published six cases of meningeal involvement from one to four months after the chancre. Similarly Lavau⁸ has reported nine cases of metachancral and pre-roseolar meningitis in syphilis, but in some at least of these the symptoms were less subjective than objective. As we are concerned only with such cases as are liable to be confused with fully-developed acute meningitis of other origin, these incomplete examples need not be further alluded to.

As instances of the unexpected appearance of acute meningitis in congenital syphilis there is the case observed by Ravaut and Darré,⁹ and in the course of chronic syphilis those of Claisse and Joltrain,¹⁰ Oettinger and Hamel,¹¹ de Caux,¹² and others.

It is perhaps too much to expect, with Bronstein,¹³ that the term acute syphilitic meningitis should be reserved for cases occurring during the secondaries, either before, during, or soon after the cutaneous eruption, but were this to be done it would bring the condition more into line with the more familiar varieties of acute meningitis.

The case that has come under our own observation is that of a patient in Fulham Military Hospital, and we desire here to record our indebtedness to Captain Carnegie Dickson, R.A.M.C., the pathologist to the hospital, for his examinations of the spinal fluid.

A. B., aged 24, was sent into Fulham Military Hospital on November 11th, 1916, by Captain Flack, bacteriologist to the London district, as a case of cerebro-spinal fever. He had complained of increasing headaches, pains in the neck, and nausea, and there was a history of syphilis some months previously. On the same afternoon Captain Flack made a lumbar puncture; clear fluid was withdrawn under pressure; films showed excess of lymphocytes and a few polymorphs, but no cocci.

On examination the next day the patient was found to be quite rational and the temperature was normal. He showed, however, all the typical symptoms of acute meningitis, intense headache, nausea, rigidity of the neck; Kernig's sign was present, and a *tache cérébrale*. It was noted that the pupils were small and unequal, but they reacted to light; the cutaneous reflexes were active, the deep neither increased nor diminished.

On the same day (November 12th) 90 c.cm. fluid was withdrawn under considerable pressure and 27 c.cm. antimeningococcal serum administered. Captain Dickson reported as follows: "A predominantly polymorphonuclear exudate with a moderate number of mononuclears, chiefly medium and small. . . . A very few degenerated 'granules,' probably cocci, but not definite. From the cytology, almost certainly cerebro-spinal meningitis."

For the next five days the patient was treated daily by lumbar puncture and antimeningococcal serum. Meanwhile it was

clear to one of us (A. C. E. G.), under whose care the patient was, that the clinical course of the case was different in several respects from the usual course of cerebro-spinal meningitis; in particular—

1. There was no pyrexia.
2. The mental condition was unusual. The cerebro-spinal fever patient is actively complaining or noisily delirious, whereas this patient was depressed and quiet.
3. The tongue was almost clean, whereas the mouth in the average cerebro-spinal fever case is characteristically foul.
4. There was no sphincter trouble and until later no vomiting.
5. There was little or no definite progress in either direction, whereas the average case of the other condition would have been getting much worse after a week or responding steadily to treatment.
6. The naked eye character of the cerebro-spinal fluid was unusual, as it was much clearer by the fourth day than could be expected except in a mild case of rapidly recovering cerebro-spinal fever.

Further, the cytology of the fluid had changed. On the fourth day it was reported that the mononuclears, chiefly small, greatly outnumbered the polymorphs; on the next day the two varieties were present in about equal numbers; at the end of the first week the lymphocytes were definitely in a considerable majority. A thick film stained for tubercle bacilli proved completely negative. No meningococci were discovered at any time.

In view of these important data the exact diagnosis was still not clear, and on November 18th one of us (S. A. K. W.) saw the patient in consultation.

On that date there was slight but definite papilloedema of both optic discs, the pupils were small and unequal, and their reaction to light was not brisk, the tendon reflexes were active, and the plantar response flexor. The other signs of acute meningitis remained as before. A diagnosis of acute syphilitic meningitis was then made, and a Wassermann test in the fluid was regarded as imperative. This was done the next day at Rochester Row, and to our surprise the result was reported as negative.

For the next ten days the patient's condition varied but little. He still complained of splitting headaches, was occasionally sick, and looked very ill. He lay in bed indifferent to his surroundings, was irresponsive, depressed, almost sullen, and only occasionally irritable when roused. The meningeal symptoms and signs remained as before.

In view of our increasing conviction of the syphilitic nature of the case, notwithstanding the negative Wassermann on November 19th, we determined to have the test repeated on December 1st, both in the blood and the fluid, which was done. Captain Carnegie Dickson reported a strongly positive Wassermann in both. Direct antisymphilitic treatment was at once commenced. On December 2nd 80 c.cm. of clear fluid were withdrawn by lumbar puncture, and 30 c.cm. of Mulford's mercurialized serum, containing the equivalent of $\frac{1}{10}$ gr. Hg, were injected intrathecally.

On the following day the patient was if anything more ill, was mildly delirious with an occasional meningeal cry; there was marked paresis of the left external rectus; ankle clonus and an extensor response were present on the right side. The right optic disc showed 5 D. of swelling, the left 4 D. Mercurial inunction was commenced in addition to the intrathecal method.

From that time, however, the case unmistakably began to change for the better. The mercurialized serum injections were continued at intervals of approximately a fortnight, and six in all were given, the last on February 16th, 1917. The Wassermann test in the fluid, and the cell and globulin tests were by that date completely negative. Corresponding to this improvement was a steady amelioration in the clinical symptoms. By the beginning of January practically the only signs in the nervous system were diplopia and slight paresis of the left external rectus, as already noted; the subjective symptoms had all but disappeared. By the beginning of February the optic discs showed no trace of the previous neuritis, while the diplopia and rectus paresis had vanished.

On February 22nd the mercurial inunction was stopped, and on March 5th the patient was discharged from hospital cured.

Before he left an accurate account of the onset of his symptoms was obtained from the patient himself, and this may be summarized in a few words. He contracted syphilis on or about August 10th, 1916, and though the signs were minimal, a Wassermann blood test was positive on August 15th. Some seven intravenous injections of kharisvan were administered, and a number of intramuscular injections of mercury, and by the end of September the Wassermann test in the blood was negative, and the patient felt perfectly well. At the end of October or beginning of November he noticed slight headache over the left eyebrow, which he associated with the strenuous clerical work he was then undertaking. In the course of one week this headache became persistent and severe. On November 8th a blood test was made, but we have not been able to trace the result. On November 10th the headache became unbearable, and that night he was kept awake by agonizing pains in the back of the neck, shooting up and into the left ear. On the 11th he was unable to get up; he felt very sick but did not vomit, and in the afternoon he was admitted to Fulham Military Hospital as above.

To summarize the salient features of this case: A previously healthy young man of 24 contracts syphilis and is

treated systematically without delay by accepted methods. The Wassermann reaction is positive in the blood; apparently no secondaries develop. In less than two months the reaction is negative, and the patient feels perfectly well. Almost exactly three months after infection he suddenly begins to suffer from severe headaches, and in the course of a few days develops the characteristic symptoms of acute meningitis. The case is diagnosed as cerebro-spinal meningitis, and is treated for a week with antimeningococcal serum in full doses. Doubts are cast on the diagnosis by the course the disease pursues and by the cytological findings in the fluid, as well as by a consideration of the history of the case. On the eighth day after admission syphilitic meningitis is diagnosed and the fluid subjected to the Wassermann test, which is, however, reported as negative. A fortnight later both in blood and fluid the Wassermann test is found to be strongly positive, and by energetic treatment with mercurialized serum and mercurial inunction the patient makes uninterrupted progress to complete recovery. He is discharged cured not quite four months after admission.

A case of this description presents several features of interest.

1. On clinical grounds a suspicion of the inaccuracy of the original diagnosis was not long in crossing our minds. There was not at any time any pyrexia; there was no vomiting till quite late in the course of the case; sphincter troubles were conspicuously absent; no rash was observed. Further, in the average case of cerebro-spinal fever the patient either sinks into coma with comparative rapidity, or becomes quickly cheerful as he improves; in other words, by the close of the first week there is usually adequate indication of the course the case is going to take. Yet in ours the patient remained for some weeks practically in the same state as on admission. He had neither restlessness nor delirium, except for a few hours at a late stage, and was perfectly rational throughout. Where cerebro-spinal meningitis becomes chronic the meningeal signs—retraction, rigidity, etc.—are as a rule very marked; emaciation is pronounced and incontinence of common occurrence. None of these phenomena was present in our case.

It may be regarded as certain, then, that the clinical aspect of the case was from the outset felt to be anomalous for cerebro-spinal meningitis.

There is a conflict of opinion as to the possibility of differentiating acute syphilitic meningitis clinically from other varieties. Desnos¹⁴ thinks it is not to be distinguished; Bronstein says the ordinary meningeal symptoms are less developed and less marked; little change in pulse or respiration occurs; the evolution is irregular, with exacerbations and remissions. De Coud holds that the symptoms are those of an ordinary diffuse meningitis, resembling tuberculous meningitis. We have already commented on the features of the case here recorded, which in our opinion separate it clinically both from cerebro-spinal and tuberculous meningitis; whether these are pathognomonic or not, whether they are exceptional in acute syphilitic meningitis or not, whether they were conceivably modified or not by the first week's treatment with antimeningococcal serum, we are not able to determine.

2. The findings in the fluid call next for remark. In none of the many examinations were cocci ever found; on the first occasion there was an unmistakable excess of lymphocytes, with a few "polymorphs." It has been shown that thereafter the fluid varied, becoming predominantly polymorphonuclear, and later again markedly mononuclear. In this connexion it is of interest to note that in Claisse and Joltrain's case the fluid was at first typically lymphocytic, after two intraspinal injections of colloidal mercury it became polymorphonuclear, and subsequently lymphocytic again. The question thus arises whether the injections of antimeningococcal serum exercised a modifying influence on the cytological content of the fluid, notwithstanding their non-specific action in this case. It is our opinion that the polymorphonuclear character of the exudate was due to the administration of antimeningococcal serum, as in our experience every case in which, owing to the suspicion of cerebro-spinal fever, this serum has been administered, has shown this polymorph reaction even when the suspicion has subsequently proved to be groundless.

The lymphocytosis is not of itself different from what is

found in the tuberculous variety. De Coud holds that in cases where the acute form of syphilitic meningitis occurs as an exacerbation from the chronic invasion of syphilis a lymphocytic finding may change to polymorphonuclear. Di Porto¹⁵ says the fibrin reticulum constantly found in tuberculous meningitis is not got in the acute syphilitic type, but we have no information on this point.

When the Wassermann test was first done in the fluid on November 19th, the result was negative; a fortnight later it was strongly positive. The sole comment we feel justified in making is that owing to unavoidable exigencies the examinations were made by different pathologists.

As far as treatment is concerned we desire to record the satisfactory results of the use of Mulford's mercurialized serum by the intraspinal route.

THE TREATMENT OF WOUNDS INFECTED WITH *BACILLUS PYOCYANEUS*.

BY

MAJOR PHILIP TURNER, F.R.C.S., R.A.M.C.,

AND

CAPTAIN G. RICHARDSON, R.A.M.C.

INFECTION of wounds by the *Bacillus pyocyaneus* is comparatively common. Sometimes the patients arrive with the wounds already infected; on the other hand, the infection often develops some time after admission. Infection may be from some previously infected wound, or it may arise from the use of infected instruments or apparatus, especially arm baths. There is also reason to suspect that some wounds are already infected with this bacillus, but owing to the presence of other organisms its growth is impeded and the characteristic appearances of the pus are not present until the local conditions of the wound become favourable for its free growth. The virulence of the organism appears to vary considerably.

Characters of an Infected Wound and Condition of Patient.

1. The suppuration is profuse, and it has a characteristic bluish-green colour which varies considerably in shade, and which stains the dressings and also very often the patient's skin.

2. There is a characteristic offensive, musty odour.

3. When this infection appears it tends to extend to other wounds in the same ward, although careful precautions are taken.

4. When it has once appeared in a wound it is very difficult to eradicate, and the healing of the wound is often greatly impeded.

5. There may be an intractable diarrhoea due to infection of the intestinal tract, presumably of septicaemic origin, and in one case recently *B. pyocyaneus* has been isolated from the blood.

6. As a result of the prolonged suppuration there may be considerable weakness and anaemia.

Owing to the above facts wounds infected with this organism have been in some hospitals isolated and treated in separate wards. The infection is not dangerous to life, and as a rule eventually the cases do well. Indeed it would appear in most cases that the wound must be granulating and showing signs of repair before the organism can grow sufficiently freely to produce the characteristic pus. Many cases in which routine bacteriological examination of pus shows *B. pyocyaneus* without clinical signs of infection have later quite suddenly discharged pus of characteristic colour and odour. Hence the infection frequently appears in wounds that are regarded

as doing well, but in which the local condition is favourable for the growth of the *B. pyocyaneus*.

Treatment of Wounds infected by Bacillus pyocyaneus.

In the autumn of 1915 cases of "blue pus" were isolated at the hospital in which we are serving, and in September there were between thirty and forty. Eusol had just been generally adopted as an antiseptic, and was used systematically in the form of baths, soaks, and for syringing in these patients. The results were disappointing; eusol appeared to have no more effect than hypertonic saline, carbolic, and other lotions previously employed.

In June, 1916, I was led to try hot eusol fomentations owing to some successful cases in which a very foul odour had been overcome in this way.

The first case on which this treatment was employed was a case of gunshot wound of the thigh and compound fracture of femur. This man, wounded June 5th, admitted June 9th, was doing very well when, on June 18th, marked and characteristic signs of infection by *B. pyocyaneus* appeared. With four-hourly eusol fomentations the colour and odour had completely gone in twenty-four hours, and the suppuration was very much less profuse. Eusol soaks were then substituted, with the result that on June 26th a faint coloration again appeared; twenty-four hours' treatment with hot eusol fomentations caused this to disappear, and it never recurred. No cultivation was taken before the eusol fomentations were started, but several were taken afterwards, and no *B. pyocyaneus* was ever found.

The second case was a patient admitted on June 3rd to the same ward with a perforating wound of the right shoulder fracturing the acromion and head of the humerus and opening the shoulder-joint. He also was doing very well when, on June 17th (suggesting infection from the preceding case), a marked and characteristic colour and odour of the pus suddenly appeared and a bacteriological examination showed a profuse growth of the bacillus. Here also with eusol fomentations the colour and odour completely disappeared in twenty-four hours and the discharge was much less profuse, but in spite of the absence of clinical signs cultivations still showed a slight growth of the bacillus. The fomentations were continued for a week when a return to eusol soaks led to a reappearance of the characteristic signs, so fomentations were resumed, with immediate disappearance of colour. The pus remained of a creamy colour until the man left hospital, but the organism, as shown by bacteriological investigation, was not completely eradicated.

Since these two cases every case of a wound infected by *B. pyocyaneus* has been promptly treated in this way without isolation. There were not altogether more than about twenty-five cases in the succeeding five months, and never more than two cases at the same time in any ward until recently, when in a small ward containing five wounded German prisoners four cases appeared practically simultaneously. Of these, when treated with eusol fomentations, two rapidly cleared up, one cleared up but recurred slightly on omitting the fomentations, while the fourth, a deep penetrating wound of the knee-joint, though very much improved still showed pus tinged with a slight blue-green colour.

The two cases first mentioned in some detail were both in a ward containing forty-two beds, at the time all occupied by wounded men, and no further cases appeared while they were in hospital. Hence it would seem that when the infection is promptly recognized and treated in this way the tendency to spread is very much diminished.

Clinical Conclusions.

The results of the treatment of these cases by hot eusol fomentations may be summed up as follows:

1. In many cases, especially in superficial wounds and where drainage is free, all clinical signs of infection by the *B. pyocyaneus* disappear within twenty-four hours or even less.
2. In a considerable number of cases a faint coloration of the pus persists for some time, often to such a slight extent that if the wound was not known to have been infected the presence of the organism would not be suspected.
3. In either of the above groups, if the colour should reappear after the fomentations have been omitted, they should be at once recommenced. In any case the fomentations should be continued for some days after all characteristic signs of *B. pyocyaneus* infection have disappeared.
4. Complete disappearance of the clinical signs and eradication of the bacillus is more likely in superficial and widely open wounds. A faint coloration of the pus is more

likely to persist in deep and sinus-like wounds, such as compound fractures; in these complete eradication of the bacillus will be more difficult or impossible.

5. It would certainly appear that the tendency of the infection to spread is very much diminished. This is the case even when a slight tinge of colour persists or when cultivation still shows the presence of the organism.

6. It is quite safe to treat these cases in an ordinary ward with other infected wounds provided that ordinary precautions, such as dressing these cases after other cases, are taken.

The question now arises as to whether the action of hot eusol is merely a bleaching action simply decolorizing the pus, or whether it really has any action in hindering the growth of, or actually destroying, the organism. That it has a bleaching action on the colour is certain, and is easily proved. It is only necessary to take a cultivation in the laboratory, and add a small quantity of eusol which has been heated nearly to boiling point. In a few seconds the colour, except in the deeper parts of the medium to which the eusol takes time to penetrate, completely disappears. Cold eusol does not have this effect. That it has some effect in destroying or diminishing its growth and virulence appears certain from the clinical facts noted above.

The treatment with hot eusol fomentations of wounds infected by *B. pyocyaneus* has a marked effect on the virulence of the organism in question. One point which has been noticed is the difficulty experienced in obtaining any pigmentation of the medium in a culture derived from a discharge of a wound which is receiving hot eusol treatment. Numerous subcultivations are necessary to restore the colour-forming properties of the organism, and one is not always successful in bringing back this characteristic feature of *B. pyocyaneus*.

Another point is that the actual growth of the organism itself is not so profuse after hot eusol treatment as it is after treatment with saline or other dressings, and also that after the former treatment one has sometimes noticed a certain tendency of the organism to die out on cultivation.

Summary of Bacteriological Results.

The results of a large number of bacteriological investigations may be summed up as follows:

1. In some cases the pus may have a bluish-green colour and an offensive odour, and yet no *B. pyocyaneus* can be found even after repeated cultivations. In these cases diphtheroid organisms are found, and it is possible that these are responsible for the colour and odour of the pus. On the other hand, it is very likely that the *B. pyocyaneus* is present but that its cultivation and recognition are prevented by the other organisms present. These cases clear up rapidly when treated with hot eusol fomentations.
2. In many cases the *B. pyocyaneus* has been found on bacteriological examination of a wound which shows no clinical signs whatever of the infection and in which its presence was unsuspected. On one occasion the pus from a wound of the foot had a bright orange colour; a cultivation was taken to ascertain the nature of the infection, and the result showed a profuse growth of *B. pyocyaneus*. This supports the view that many wounds may be infected, but that a certain stage of healing or other local condition may be necessary for the profuse growth of the organism and the production of the ordinary clinical signs.
3. If cultivations are taken from infected wounds while the treatment with hot eusol fomentations is in progress there is an evidence of decreased virulence, as shown by slower growth and by diminished and slower production of colour.
4. In some cases if cultivations are taken every two days the organism may entirely disappear. This is more likely to be the case in shallow and superficial wounds, and may occur in two or three days or after a slightly longer interval. In deep and sinus-like wounds a faint growth may persist for a very long time, and is usually associated with a faint greenish tinge in the pus. It may also persist in the entire absence of all clinical signs.
5. Complete eradication from deep wounds is difficult. A cultivation may be negative, and even though the treatment is continued and clinical signs absent, later cultivation may give a positive result.
6. Clinical and bacteriological evidence combined show that virulence of the organism varies considerably, and

that a cultivation may show its presence in the absence of clinical signs. Under these circumstances it is practically non-infective, and does not harm other patients or the wound. It is when the clinical signs are present that the pus is infective, and the organism is likely to spread to other patients and seriously to retard the process of healing.

Method.

1. As soon as a wound is suspected to be infected a specimen of the pus is sent to the pathological laboratory for examination. If the clinical signs are definite, treatment by hot eusol fomentations is commenced at once. In a doubtful case the result of the examination may be awaited.

2. The fomentations must be of sufficient thickness and size; they must be as hot as the patient can stand, and must be changed four-hourly. A 5 per cent. solution of eusol heated to boiling point is employed. The wringer should be of canvas or strong calico, since ordinary wringers of linen or flannel are rapidly destroyed.

3. When the wound is deep or sinus-like, or when a slight coloration persists, the wound may be syringed twice daily with eusol as hot as the patient can bear, or packs of eupad powder wrapped in gauze and moistened with hot eusol may be employed in addition to the fomentations. The latter is often very effective.

4. Frequently the odour and colour will completely disappear in twenty-four hours or less, but the fomentations should always be continued for at least three or four days after the disappearance of the clinical signs.

5. When the fomentations are omitted, eusol or saline soaks may be used; but if there is a return of colour and odour, treatment by fomentations must be resumed.

6. A bacteriological examination of the pus should be made every two or three days as a guide to treatment. Cases in which the clinical signs of the infection are absent but the organism is found on bacteriological examination are probably harmless, but it is wise in these cases to continue the eusol fomentations for a long period.

NOTES ON IONIC MEDICATION AND THE METHOD OF ADMINISTRATION.

By LEIGHTON KESTEVEN, M.R.C.S.ENG.,
SYDNEY, N.S.W.

LEWIS JONES, in the preface to his handy little book on ionic medication, laid it down that we need not greatly concern ourselves as to whether there is effective penetration of ions or not, but that the procedures he describes have been followed by results of value. From the incontestably satisfactory results obtained by ionization as compared with simple electrolysis, I think it is impossible to doubt that such penetration does take place.

My experience in the treatment of ear disease, for instance, has given me results that I could certainly have obtained by no other method. None of the authorities on middle and inner ear troubles make more than the most cursory mention of electricity as an aid in treatment, and ionization is barely suggested as feasible at all, yet I have found it of infinite value in arresting some of the gravest symptoms in these cases.

Resolution of inflammation, release of adhesions, and general bactericidal action are the things to be aimed at in dealing with the ear. Galvanism has done some good, but the great value of ionization lies in its sclerolytic effect. This can be secured by no perfunctory use, however, and I think the absence of satisfactory results contributed so far is somewhat due to the insufficiency of the technique employed. For instance, it is recommended to ionize the tympanum by the use of a probe tipped with cotton-wool soaked in the fluid to be employed. This is futile; the cotton-wool cannot hold enough from which to derive sufficient ions to be effective. The proper method is to lay the patient's head sideways on the table, and to fill the external meatus with the solution employed, then the current is passed through it, thus ensuring a constant supply of the required ions. A small probe insulated to its tip will carry the current into the solution.

Great relief may be obtained in all classes of middle-ear catarrh in this way by the use of a solution of zinc iodide (30 per cent.) with 3 to 4 milliamperes of current.

Zinc iodide is a colourless and stable compound made by boiling zinc and iodine together in water in the proper proportions. It is non-irritative, and soothing in action. Iodine being an anion and zinc a cation the current must occasionally be reversed to get the benefit of both the elements, removing the anode during reversal to avoid the shock. In acute cases the current may be kept on for five to ten minutes, in chronic for twenty.

The relief of pain in the acute cases is very marked after the current has run for a few minutes. In the more recent cases the relief comes speedily, perhaps half a dozen applications suffice; in those of long duration weeks, and even months, are called for, and it is not justifiable to cry off without prolonged trial in the most apparently hopeless cases. Tests with the forks may any day reveal some little amelioration encouraging one to persevere.

A man had been stone deaf for twenty years from labyrinthine trouble in one ear and middle-ear disease in the other, with fixation of the ossicles. I ionized the latter for nearly three months without a sign of improvement, occasionally inflating with compressed air at 20 lb. pressure. Just as he wanted to give up and I was beginning to despair, eighty-five days from the beginning of treatment, he told me he had heard the clock ticking, and on testing I found he had slight aerial audition with the C² fork. At the end of six months he could plainly hear loud conversation, and I sent him back to the bush, as that was the most that could be attained, but it made life worth living.

In the functional deafness caused often by nerve exhaustion, the result of mental trouble, ionization gives much relief, acting in some cases like magic. A man who has great business and family troubles comes to me periodically for an "ear pick-me-up," and goes away hearing and refreshed after two or three ionizations of zinc and iodine *plus* a little faradic.

Many mastoid cases, I am convinced, if taken at a reasonably early stage, can be arrested and operation avoided by ionization with an absorbefacient bactericide. Mercuric iodide (HgI₂·2KI) presents such a compound, and can be administered in 1 in 500 solution for periods of half an hour morning and evening with 5 milliamperes current.

A young woman came to me with all the usual symptoms of fairly advanced mastoiditis and I applied this treatment. The pain left her after the second application but returned in the night. That morning I kept her under for an hour and a half; all pain had then gone and she had no return of it during the progress of the case. The swelling and tenderness were very great when she came first, but subsided from the second day; the tinnitus disappeared on the first evening, and, though there was very marked sagging of the posterior wall she recovered entirely within three weeks. She would not allow me to puncture the tympanum. She has no impairment of hearing now, a year after the treatment, and transillumination through the meatus shows no dark area.

The current here, to my mind, clearly carried the ions direct into the mastoid. In purulent otorrhoea this germicidal action is manifested in the rapid diminution of the leucocytes and lymphocytes under ionization by zinc and iodine.

Ionization with a 2 per cent. solution of alum is useful in relaxation of the tympanum. I have used arsenic ions in two cases of tuberculous middle-ear trouble; in one instance without result, in the other with very marked benefit.

The aural vertigo so often indicative of labyrinthine loss of couple, is generally, but slowly, relieved by the mixed continuous ionization and mild faradic current. Labyrinthine tinnitus can also be greatly relieved and often removed by iodine ionization. The positive pad should be placed behind the mastoid, and the current (5 milliamperes) sustained for half an hour on alternate days for a week or so. If pain is at any time urgent immediate relief can be given by ionization with cocaine. Morphine will act similarly, but more slowly.

Goitre has been tackled with varying success by radium and x-ray therapy. It yields to ionization in a satisfactory manner, but the treatment is long and tedious.

In a girl of 17 with marked enlargement of both lobes of two years' standing, I got complete recovery after four months' application on alternate days. I used an aluminium anode 6 in. long, 1½ in. wide, curved to fit the neck, covered with four thicknesses of lint kept saturated with 5 per cent. solution of zinc iodide, with 15 milliamperes of current for an hour at a sitting.

In another case of many years' standing I have reduced the enlargement by half after twelve months' work, and, as it is slowly but steadily decreasing all the time, I hope to get it down entirely.

These are typical of a good many similar cases I have under observation, and are distinctly encouraging; goitre is a great disfigurement, and patients will gladly endure many things to get rid of it.

Following up my experience of the excellent results obtainable by the efficient application of ionic medication, and its potency in promoting the resolution of inflammation and the infiltrations and exudations resultant therefrom in ear troubles, it occurred to me that neoplastic growths offered a suitable field of research owing to the controlling power of the ions on benign tumours, such as adenomas.

In acute tonsillitis, using a curved aluminium probe insulated to within half an inch of its end, round which cotton-wool is wound and dipped frequently in 5 per cent. zinc iodide solution, I pass a 15 to 20 milliampère current through the tonsil for five to ten minutes. Relief from pain is speedy, and the tumefaction subsides so rapidly after the applications that the tonsil will be nearly its normal size within forty-eight hours after the first application. Two or three applications are, as a rule, enough. In chronic indurated cases longer treatment is called for, say eight or ten times on alternate days with a 10 per cent. solution. The negative current should be passed through the probe, as iodine is an anion, and a padded cathode placed at the back of the neck.

Enlargement of the turbinates can be reduced by the zinc iodide, but, owing to the more sensitive nature of the nasal membrane, only 2 per cent. solution should be used. About two or three minutes at a time is all that should be given, and a carbolic powder should be blown in afterwards to allay any smarting. By this method the knife and the cautery may often be avoided. The Eustachian tube can be ionized with a Eustachian catheter perforated at the sides for the last quarter-inch, and closed at the end. This is connected to a fine tube holding the ionizing fluid, with a fine wire in it to carry the requisite 3 milliampère current. It is best to use potassium iodide, as the zinc might do harm if swallowed. Five minutes at a time is ample, and will often relieve mid-ear tinnitus.

Enlarged prostate can be treated with success by this method, and I have described elsewhere a special electrode I devised for the purpose. This, particularly in old cases, is a tedious job, requiring great patience to induce the sufferers to persevere in treatment. The sensation is not very pleasant, and some local anodyne is occasionally called for; but the good results are, in my experience, indubitable. Symptoms which make life a misery are relieved without risk to life.

Either aluminium or copper wire an eighth of an inch thick can be used for the probe electrodes. An easy way of insulating them is to dip them into a saturated solution of celluloid in acetone. The points can then be scraped bare with the knife for the cotton-wool at the ends. The celluloid will not bear boiling, but can be sterilized with 30 per cent. carbolic solution.

A CASE OF ACHOLURIC JAUNDICE TREATED BY SPLENECTOMY.

By ROWLAND HILL, B.A., M.D., M.R.C.P.LOND.,

TEMPORARY SURGEON, R.N.,

ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, AND
MEDICAL REGISTRAR, ROYAL VICTORIA HOSPITAL, BELFAST.

REPORTS of cases of acholuric jaundice treated by excision of the spleen are comparatively few in British medical literature, and this impels me to publish an account of a case so treated with much immediate and, I hope, permanent improvement in the patient's general condition.

Stoker L., aged 23, contracted dysentery (bacillary?) in Gallipoli in August, 1915; as the acute symptoms of this affection subsided he became slightly jaundiced. After some weeks of treatment in a naval hospital he returned to duty, the jaundice having entirely disappeared.

On August 6th, 1916, he was seized with pain in the right hypochondrium and in both loins; he was found to have marked jaundice; the temperature was 104° F. He was admitted to hospital the next day, being sent to the surgical wards as a case of "acute cholecystitis." He appeared to be in great pain, was sweating profusely, and his temperature was 101° F. There was distinct yellowing of the conjunctivae and a less marked yellowing of the skin; there was tenderness over the abdomen and in both loins, and distinct fullness of the upper

part of the abdomen; no rigidity of the abdominal muscles was present. He had retention of urine; a catheter specimen had specific gravity 1025, was alkaline, and contained a trace of albumin and a small amount of bile pigment, but no sugar. Nothing abnormal was found in any of the other organs, and the stools were normal in colour and consistency.

On August 8th well-marked haematuria commenced and continued until August 11th; no calculi could be detected in the kidneys or bladder by x rays.

Exploratory Laparotomy.

On August 11th, the haematuria, jaundice, and fever still being present and there being now a distinct tumour extending across the upper abdomen from the left hypochondrium, exploratory laparotomy was performed. On incising the tissues of the abdominal wall they were found to be bile-stained and oedematous, and on opening the abdomen the spleen was seen to be greatly enlarged, extending across the middle line, but no inflammatory lesion of the gall bladder, appendix, kidneys, or gastro-intestinal tract could be detected. The abdomen was immediately closed. The patient's general condition improved somewhat after the exploratory operation, the temperature fell, the blood and bile disappeared from the urine, and during the whole of the time he was subsequently under observation no abnormal constituent was found in the urine. There was still slight tingeing of the conjunctivae, and the patient became more and more anaemic. On August 17th he was transferred to my care, and a "fragility" test of the red blood cells was carried out, with the following result:

Saline Solution.	Patient's Cells.	Control Cells.
0.4 per cent. ...	Complete haemolysis	Complete haemolysis.
0.425 " ...	" "	Partial haemolysis.
0.45 " ...	" "	No haemolysis.
0.475 " ...	" "	" "
0.5 " ...	Partial haemolysis	" "
0.525 " ...	" "	" "
0.55 " ...	" "	" "
0.575 " ...	No haemolysis	" "

The serum was distinctly bile-stained. A blood count showed:

Red cells ...	3,090,000
White cells ...	5,200
Haemoglobin ...	45 per cent.
Colour index ...	0.75
Differential count:	
Polymorphs ...	58.4 per cent.
Small mononuclears ...	34.3
Large mononuclears ...	6.0
Basophiles ...	1.3

Three nucleated reds, some macrocytes and microcytes, some poikilocytosis, and some polychromatic staining found in the film.

At this date the spleen extended down to the level of the iliac crest in the left nipple line and across the mid-line of the abdomen. Subsequently the Wassermann test was found to be negative; there was no pathological agglutination of the enteric group of organisms, and no dysentery organisms were found in the urine or faeces.

The patient was treated for a month with iron, arsenic, cod-liver oil, etc., without any marked effect on the anaemia, and at the end of this period, slight jaundice of the conjunctivae being still present, I advised him to submit to splenectomy.

Splenectomy.

On September 30th Surgeon-General Sir Watson Cheyne removed the spleen, which weighed 22 oz. A microscopical section showed a general increase of the fibrous tissue, with atrophy of the Malpighian bodies and a marked free-iron reaction with potassium ferrocyanide.

The condition of the patient's blood improved at once after splenectomy, and by October 6th the haemoglobin content had risen to 55 per cent., and all trace of poikilocytosis had disappeared. Convalescence was slow but progressive, and the blood, examined again in January, 1917, revealed a normal picture except that the abnormal fragility of the red cells was still present.

In August, 1917, I heard from the patient that he has had no jaundice since operation, and is feeling quite fit.

The case appears to have been one of the acquired type of acholuric jaundice, as prior to the attack of dysentery there was nothing in his own or his family history to suggest that he was suffering from the familial type of acholuric jaundice.

In conclusion, I desire to express my thanks to Fleet Surgeon J. Chambers, R.N., for permitting me to record the case, and to Staff Surgeon S. F. Dudley, R.N., for much assistance in the clinical pathology of the case.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF CONGENITAL TRANSPOSITION OF THE HEART.

ROBERT Y., aged 17, was admitted to this ship suffering from phthisis. I found that there was no cardiac impulse at all on the left side, but the apex beat was felt in the fifth interspace under the right nipple; the impulse was of a diffuse nature; the sounds were very indistinctly heard to the left of the sternum. At the base the sounds were faint, whilst at the apex they were well heard; no murmur was detected in any area. Percussion showed the area of cardiac dullness to extend from the fifth right interspace to the sternum, but no dullness was made out to the left of the sternum. The upper limit of the heart was difficult to define on account of the pulmonary dullness in that region. The liver and spleen were in their normal positions.

From the above it seemed that the heart was the only organ transposed, and this was confirmed by x-ray examination. The plate was clear on the left side of the chest, but on the right side there was a shadow which merged with the liver shadow below, and which had a curve to the left resembling that thrown by the normal right side of the heart. The patient did not seem to have any inconvenience apart from some breathlessness on exertion, but this might partly be due to his lung condition.

It was thought at first that the heart had been drawn over to the right side by contraction of the lung due to the phthisis present, but further examination was against this. The chest wall was hardly retracted at all, while with such a complete drawing over of the heart one would have expected much less lung tissue to be present than was made out from the physical signs. One would also have anticipated the presence of some murmur due to twisting of the vessels, but no such murmur was detected.

The condition seemed to be congenital, and this opinion was strengthened by the patient's statement that a doctor had remarked about four or five years previously that his heart was in an unusual position. I think the case is worth recording in view of the rarity of transposition of the heart alone without any of the other viscera.

ROBERT AITKEN, M.D.,

H.M. Hospital Ship *Plassy*.

Temporary Surgeon R.N.

STERILIZATION AND PREPARATION OF CATGUT.

I CAN confidently recommend the following method as one producing a clean ligature or suture material, and an ideal result, as far as tensility and necessary durability are concerned, not to mention the comparative diminution of chemical impregnation, which has been a frequent and fertile source of irritation in the depth of aseptic wounds:

1. Raw catgut, free from fat, as supplied by surgical purveyors, is wound up in loose rolls and placed in a Mayo Robson's or Jellett's bomb, which is almost filled with a mixture of equal parts of rectified spirit and ether. The bomb is then placed in a kettle of hot water and boiled for half an hour for fine catgut, and for one hour for the larger sizes.

2. The catgut is then removed from the bomb by a sterilized forceps and placed in a glass bottle containing a solution of 90 per cent. absolute alcohol and 10 per cent. formalin (40 per cent. solution). The catgut is kept in this mixture for forty-eight hours.

3. It is next similarly taken out of the alcohol-formol mixture and immersed and washed for half an hour in a basin of pure ether.

4. Finally, it is placed in a bottle filled with equal parts of ether and alcohol, in which it is retained until required for use.

JOHN O'CONOR, M.A., M.D., T.C.D.,
Senior Medical Officer, British Hospital,
Buenos Aires.

TREATMENT OF SCABIES.

THE following is the method of treating scabies I have carried out for a good many years. It is quick, simple, cheap, and only one working day is lost.

The morning the patient is seen he is rubbed all over with sulphur ointment; 3 jss is plenty, made with vaseline

3 x, sulphur 3 ij. No bath before is necessary. He then puts on the same infected clothes, not to soil clean ones, wears the underclothing for twenty-four hours, and then has a hot bath with plenty of ordinary soap; when dry, he puts on all clean clothes and returns to his ordinary duties. Before getting into the bath he collects all his dirty clothes and things he has been using the last few days, including bedding, for disinfection. If no disinfectant is available they are put into an izal solution for twenty-four hours; he then washes and dries them.

Under this treatment I had not to send a patient to a hospital, never saw a case of sulphur dermatitis, nor the disease spread to messmates.

G. H. FOOT, M.D.,

Southampton.

Fleet Surgeon (retired).

TONSILLECTOMY.

IN an article in the BRITISH MEDICAL JOURNAL, August 11th, p. 184, the view is submitted as hardly assailable that surgeons who claim to be able to completely enucleate every tonsil with the guillotine are in error, and go to an unjustifiable extreme. The evidence in favour of this view is that other surgeons combine partial dissection with the use of a guillotine. I submit that the evidence in no way warrants the conclusion.

Without entering upon the question of the superiority of one method over another in results, it will be admitted that in hospital out-patient practice the saving of time, the choice of anaesthetic, and the safety of the patient in returning straight home, must lead to the use of the guillotine method. I contend that some surgeons find that after the experience of some thousands of cases they are able, with the guillotine, to deal with every case with which they are confronted, both in child and adult, and require to use no other method.

In my opinion enucleation of the tonsil by the guillotine, in the more difficult cases, requires more practice, and what might be called "knack," than perhaps any other surgical operation. I admit that the length of practice necessary for this complete proficiency with the guillotine would not be worth undertaking for its own sake while there is the method of dissection to fall back upon. But the hospital tonsil day comes round and round, and when this degree of proficiency has been arrived at all other methods appear superfluous—louger, and less safe.

I would suggest that, with few exceptions, the two camps of guillotine or dissection advocates correspond with those continually engaged in hospital out-patient tonsillectomies, and those freed of this duty.

Bristol.

H. BODKIN.

AN UNUSUAL CASE OF STRANGULATED HERNIA.

A MAN, aged 45, was admitted to Kingston Victoria Hospital on August 13th. He had noticed a small lump in his right groin for several months. Suddenly, under effort at lifting, it became large and hard, making him vomit and groan with pain. I found a tumour above Poupart's ligament extending up and out to the anterior superior spine, taut as a drum, and immobile. There was a dimple over the external ring where the intercolumar fibres constricted it. No attempt at taxis was made. The gut at operation was found coal-black but shining, and was returned.

The hernia was congenital, with a lateral sac between the two obliques, interstitial, intraparietal. The gut in the side sac was twisted as well as strangulated. The loop in the scrotum was much less tense and cyanosed; the neck of the sac was very narrow, and creaked like cartilage when snicked. More than a couple of feet of gut were involved. The case was puzzling at first. The man has made a good recovery.

Kingston-on-Thames.

J. E. S. BARNETT, F.R.C.S.

CONGENITAL ABSENCE OF ANTERIOR ABDOMINAL WALL.

THE following case may be of some interest to the readers of the JOURNAL.

On August 13th I was called to a confinement—Mrs. H., 10 para—being informed by the messenger that "there was something coming which was not the baby." On my

arrival I discovered fetal intestine presenting at the vulva. Abdominal palpation showed the child lying transversely with its head in the left iliac fossa. With the kind assistance of Dr. K. I. Shalaby, who administered the anaesthetic, internal version was performed and the child delivered. It proved to be a teratosomian, with complete absence of the anterior abdominal wall. The placenta was directly attached to the abdominal viscera.

This condition appears to be sufficiently rare to merit publication.

Rebichus.

WOUNDS OF THE LUNG IN WAR.

EARLY in the war it became clear from Sir John Rose Bradford and Dr. T. R. Elliott's observations that the lessons of the South African war enunciated by Sir G. Makins as to the prognosis and treatment of haemothorax might require considerable revision. The chest wounds in the Boer war were mainly due to bullet wounds and infection rarely followed unless the chest was tapped or opened, and therefore, generally speaking, the policy of non-intervention held the field. It still is true that closed bullet wounds of the chest seldom become infected, but in the present war large and open shell wounds of the chest play such an important part that wounds of the lung formerly regarded as benign now show a high mortality. Thus, in a recent monograph based on the experience of the French Medical Service, PIERRE DUVAL¹ points out that the total mortality of 3,453 cases of wounds of the lung has been 688, or 20 per cent.; the mortality diminishes as the distance from the fighting line increases, being estimated at 25 to 30 per cent. in the casualty clearing stations, at 18 to 20 per cent. in the motor ambulances, and at 10 to 12 per cent. in the base hospitals round Étapes. No less than 60 per cent. of the deaths occur within the first two days, and these are almost entirely due to haemorrhage and mechanical interference with respiration. The frequency of early death from haemorrhage has urgently raised the question of surgical interference, and while there seems to have been general agreement at the discussion at the Société de Chirurgie (1916-17) that such a course was logically correct, the authorities fell into two camps as to the desirability of its practical application: Hartmann led the supporters of the conservative standpoint, while Duval urges, in favour of opening the chest in order to stop the bleeding, a table of 34 cases of thoracotomy (17 from his own practice), with 67.7 per cent. of recoveries. The surgical technique is obviously an essential factor in deciding the question of operative treatment in wounds of the chest; in pre-war times the fear of pneumothorax dominated the position, and led to the employment of elaborate apparatus of German origin designed to maintain a low atmospheric pressure around the operation field, and to raise the intrapulmonary pressure. The object of these measures—namely, absence of pulmonary collapse—when attained, has the grave disadvantage that it interferes most materially with necessary examination, manipulation and treatment of the lung. Duval's experience has changed this point of view, and would revolutionize the treatment of lung wounds; the production of a slow and progressive pneumothorax is not specially dangerous, allows a complete examination of the lung, which can be brought out of the operation wound, and, unlike laparotomy, does not cause shock or a fall of arterial blood pressure. Further statistics of the results of the early treatment of haemorrhage due to wounds of the lungs by thoracotomy as advocated by Duval will therefore be awaited with great interest.

The sequels of wounds of the lungs, though a familiar subject, has been attractively dealt with by EMILE MALESPINE,² who analyses 294 cases seen at a base hospital

three months after the original injury, an interval which ensures that the results are uniformly remote. Empyema was, of course, the commonest and most important sequel, others being varying degrees of pleuritic adhesions, pulmonary fibrosis and emphysema. Secondary haemoptysis occurred spontaneously in cases with an intrapulmonary projectile, as a result of its extraction, and at the onset of an interlobar pleurisy. Although the clinical manifestations may suggest the presence of traumatic tuberculosis the available evidence is against this conclusion. Functional disturbances—pain, dyspnoea, and cough, in the order of their frequency—are common, most persistent after the closure of the wound, and extremely difficult to cure.

SYPHILIS AND THE ARMY.

We have already had occasion to notice a good many of the books issued in the French *Collection Horizon*, and in nearly all cases have been able to speak of them in high terms of praise. They are small books, and may be studied with special advantage by members of the Army Medical Service. The volume we are now noticing, on syphilis in the army,³ by Dr. THIBIERGE, is not inferior to any of its predecessors. With Matthew Arnold, we cannot but concede to our allies with admiration the gift of "sweetness and light" in what they write, even if, as in the present case, it be but a volume on war medicine. Dr. Thibierge writes with a simple clarity and a reasonableness that carry conviction.

If in form the French army practice with regard to the treatment and the regulations regarding syphilis differs from ours, on analysis it is seen that the methods of the two armies are to all intents and purposes the same. We in England would perhaps lay more stress than does Dr. Thibierge upon the value of the Wassermann test, yet while in discussing the frequency of syphilis in the general population before the war an English writer would almost certainly have called attention to the data afforded by the Wassermann test as to the frequency of the disease in the great cities of the empire, it has to be admitted that we cannot produce adequate figures to demonstrate that since the war the incidence of the disease has increased. With Dr. Thibierge we have to be content to state our belief that this is probably the case, basing that belief on the experience of the individual practitioner.

The author deals with his subject under the following heads: Frequency of syphilis in the army; origin of syphilitic contagion in the army; the national danger of syphilis; social consequences of the disease; symptoms and diagnosis (50 pp.); treatment, special conditions governing treatment in the army; mercurial treatment, arsenical treatment, combined arsenical and mercurial treatment, plan of treatment at different periods of this disease; technique of intravenous injection (in all 70 pp.); hygiene; prophylaxis, including instruction, supervision of cases after treatment; instruction of troops regarding venereal disease, personal precautions, establishment of local centres for the treatment of venereal disease affecting the civil population, and supervision of prostitutes.

NOTES ON BOOKS.

THE sixteenth edition of *Minor Surgery and Bandaging*,⁴ originally written fifty-six years ago by Christopher Heath, and afterwards kept up to date by Mr. Bilton Pollard, has now been prepared by Mr. MORRISTON DAVIES, whose name was associated with the last edition. The whole work has been revised, but, except for the final chapter on gunshot wounds, the general plan is unchanged. Without materially altering the scope and character of such a compendium it would not be feasible to deal in any general way with the great mass of knowledge which has been acquired since the war on the subject of military surgery. The chapter on wounds and their infections may, however, prove useful as a slight introduction to the subject for beginners. The character of the work as a whole is too well known to need description here. House-surgeons, dressers, and junior

practitioners, for whom it is intended, will find in it a large amount of technical information upon the various procedures which are comprehensively styled "minor surgery." The chapter on anaesthetics, contributed by Dr. Dudley Buxton and Dr. Felix Rood, in common with the rest of the book has been revised in the light of recent advances in technique.

The activity of the pathological department of the College of Physicians and Surgeons of Columbia University, New York, under the direction of Dr. W. G. MACCALLUM, is shown by a volume of *Studies*⁵ containing reprints of thirty-four papers representing work done during the collegiate years 1914-16, and published in 1915. It is not possible to give any detailed account of these publications, many of which are of great clinical and pathological interest. There is an excellent account of periarteritis nodosa by Dr. A. R. Lamb, and several papers of some importance by the Director of the department, to mention but two of the contributors to the volume, which may be recommended to the attention of all pathologists.

WAR PENSIONS STATUTORY COMMITTEE.

THE report of the War Pensions Statutory Committee for the year 1916 has just been issued in Blue Book form. In point of fact the report covers the whole period during which the Committee carried out the functions assigned to it by the War Pensions Act of 1915. The Committee was constituted in November, 1915, and in consequence of the setting up of the Ministry of Pensions it finally relinquished its functions on August 31st of the present year. The Act establishing the Ministry of Pensions, which became law on December 22nd, 1916, provided that the powers and duties of the Statutory Committee should be exercised and performed under the control and in accordance with the instructions of the Minister, and that the Committee should render to the Minister advice and assistance when requested. At the conclusion of their task the Committee, while regretting that they have not themselves been able to complete the work they had begun on behalf of the disabled sailor and soldier, and the dependants of those who have fallen, express the belief that the experience gained both by themselves and the local committees set up by them will be of lasting service and will render the task of the Minister of Pensions much easier than would otherwise have been the case.

Medical Treatment of the Disabled.

The report contains, *inter alia*, an account of the work done by the Special Disablements Subcommittee. The conclusion was soon reached that the medical treatment of disabled men must as far as possible be carried out on national lines. Experience in this country and in France showed that after their discharge it was exceedingly difficult to make sure that the men could be collected for further treatment. It was accordingly resolved that men ought not to be discharged from the forces so long as they still required active medical treatment. The Committee, therefore, in pursuit of this policy, asked that the War Office should retain full responsibility until the men injured during service had been as far as possible restored to health. A conference, followed by a deputation, failed, however, to convince the War Office that this was the right solution of the problem, and the Committee were compelled to make other plans. Early in 1916 the Insurance Commissioners were approached, and a provisional agreement was come to for special treatment for discharged soldiers; but until the question as to the time of discharge was settled by the War Office no final arrangements could be made. In the meantime certain groups of disability were provided for. Thus the Insurance Commissioners undertook the domiciliary and institutional treatment of insured sailors and soldiers discharged suffering from tuberculosis, while the uninsured were provided for by the Local Government Boards for England, Scotland, and Ireland. The totally blind were treated in London at St. Dunstan's, and at an affiliated institution in Edinburgh. The provision of artificial limbs after amputation

was dealt with by the Roehampton Hospital and kindred smaller institutions, while paraplegic cases were taken at the Star and Garter Hospital at Richmond, established by the Red Cross Society. Upon the advice of the Board of Control certifiable mental cases were distributed among the existing public asylums, a small sum above the cost of maintenance being provided so that the men might not be placed on the pauper roll, but become a kind of private patient under the euphemism of "service patients." The disposal of neurasthenic cases naturally gave rise to much anxious thought on the part of the Committee, since it was open to question whether the grouping of such cases together in institutions might not aggravate the condition. Last autumn, however, at the instigation of the chairman of the special medical board for neurasthenic cases, an experimental institution was established in which such men could be placed side by side with crippled and maimed soldiers. The Red Cross Society provided the necessary capital, and the authorities of the Maida Vale Hospital for Nervous Diseases undertook the management of such a hospital at Golders Green.

Industrial Training.

In the paragraphs on training the principle is laid down that as far as possible some curative manual training should be attempted in connexion with the treatment of orthopaedic cases, a point often referred to in articles on this subject in the JOURNAL. The Committee urged on the War Office that they should allow this special form of instruction to take an industrial bias before the man's discharge, so that technical training could be continued afterwards. But looking to the varying circumstances of disabled men, the problem of their training was recognized as being one of great perplexity. It was hoped that many men would desire to be trained in agriculture, but so far this hope has not been realized in any marked degree. Owing to the great dearth of labour almost every discharged man has been able to get work without training, with the result that might have been expected by students of human nature. Thus we learn that, although the technical schools throughout the country have readily offered classes in various subjects, the experience of the local pensions committees has been that they can persuade only a very few men to avail themselves of the offer. This is not very satisfactory, and the local education authorities have been called in to assist in organizing the training of partially disabled men, in co-operation with the local pensions committees.

Employment for the Disabled.

Under the heading of employment the report states that it was considered undesirable to start employment bureaux specially for disabled men if the national system of employment exchanges could deal with them satisfactorily. The figures given suggest that they have been able to do this. There are more than 400 exchanges in the United Kingdom, and as they are in touch with employers in every district, and in every industry and occupation, they are in a position to give substantial assistance to disabled soldiers whose injuries are not so severe as to preclude them from normal industry. Large numbers of partially disabled men have already been absorbed into munitions work upon their discharge, and the Ministry of Munitions has appointed a training section for cases needing instruction before beginning work. While the war continues little difficulty is expected in finding employment for most disabled men who are reasonably efficient; but this state of affairs is not likely to outlast the war, since whatever the general condition of trade and industry, employers will probably be inclined to prefer able-bodied men for all processes which are usually carried out by male labour. The Statutory Committee and the Labour Ministry therefore laid their heads together, and proceeded to collect detailed information with regard to industrial processes in which men disabled in varying degrees could do as good work as able-bodied men. When this information has been gathered it is proposed to press the claims of disabled men upon employers who notify vacancies in which such men could render efficient service. In furtherance of this idea it is hoped that simple adaptations of machinery or methods may be devised which would enable certain classes of wounded men to be employed in tasks which would otherwise be closed to them.

British Medical Journal.

SATURDAY, SEPTEMBER 29TH, 1917.

THE SHORTAGE OF MEDICAL STUDENTS.

ACCORDING to memorandums¹ recently submitted by the Committee of Reference and by the Central Medical War Committee, there seems to be now more than ever grave reason to fear that the supply of newly-qualified medical men and women whose services will be available to satisfy the national needs during the next few years will not be adequate. This possibility was indicated, though not very emphatically, in a statistical table² issued last March by the President of the General Medical Council. Here it appeared that the total number of men and women likely to qualify as medical practitioners in Great Britain and Ireland during the year 1917 was about 1,250, less than 1,020 for the year 1918, and only 833 for the year 1919; the average number of medical men added to the *Medical Register* annually having been about 1,100 in the times before the war. An earlier announcement of this probable shortage was made at the end of last year³ by Sir Donald MacAlister in his presidential address to the General Medical Council. On that occasion he told how he had instituted a census of medical students in May, 1916, and as a result had called the attention of the military authorities to the shortage of medical students in their second and third years of study, suggesting certain steps to prevent any further depletion. The Army Council considered these suggestions, and issued orders permitting registered medical students, called to the ranks otherwise than as combatants for service abroad (men, that is to say, not classed fit for general service), to enrol in an officers' training corps and receive their military training under conditions not incompatible with professional study at home. Still earlier in the war, that is to say, in November, 1915,⁴ something had been done under Lord Derby's recruiting scheme to relieve the shortage of newly-qualified medical men that had long appeared to threaten even at that time. The publication by the statutory professional committees of the memorandums referred to above marks a moment opportune for the consideration of the whole matter.

How far have the measures hitherto adopted to counteract the imminent shortage of newly-qualified medical men been successful? To but a small extent, must be the answer. Before the war the average annual wastage of doctors was about 900. The most recent figures collected go to show that only about 900 men are due to qualify in the present year, 1917, and only about 900 more during 1918. The shortage of newly-qualified men will be at its zenith in 1919, when, according to the Central Medical War Committee, no more than 519 of our male medical students are due to qualify; the figure for 1920 is now said to stand at nearly 800, and that for 1921 at perhaps 700. It is apparent, then, from these figures that the actual shortage of first, second, and third year students,

as compared with normal times before the war, represents, numerically, a very serious reduction. The number of medical students who are likely to become qualified medical practitioners both this year and next year is only enough to make good the normal wastage among civil practitioners in times of peace, quite apart from the pressing demands of our armies in the field, and the heavy casualties among officers of the R.A.M.C. To appreciate this position it must be remembered that the supply of medical men for the needs of the civil population has now been reduced to the minimum consistent with safety, while practically all new additions to the ranks of the medical profession by the qualification of students are at once requisitioned by His Majesty's forces, and are not available to make good the normal average wastage of the doctors required by the civil population at home. Since there is now no longer any reserve of medical men who have retired from practice but are still able to return to work—for us to fall back on, and since there is a large abnormal wastage of qualified medical practitioners arising directly out of the war, the outlook for the future is even less satisfactory than appears from the figures quoted above. We say this without in any way depreciating the valuable services that will be rendered by the few hundreds of women medical students likely to qualify during the next few years. It must be recognized that, considered as medical practitioners, members of the two sexes are not yet generally interchangeable.

To what factors is the shortage of medical students to be attributed? Not, apparently, to any lack of young men anxious to enter the medical profession. As the memorandum of the Committee of Reference shows, early in 1916 there were 1,422 first-year men students, due in the ordinary way to qualify in the year 1921. But it now seems probable that not more than half these will become qualified in that year. The reason for this is threefold. Last February an Army Council Instruction was issued authorizing the calling up of medical students classified as B1; a number of first and second year medical students who had previously been rejected for military service or put in class C have been re-examined under the Military Exceptions Act, placed in higher categories, and called up; while first-year men as they reach the age of 18 have been called up. It is further to be remembered that a certain number of medical students who enlisted or took commissions before the Military Service Acts came into force are still serving as combatants, not all of them having been allowed to return to their medical studies. We would here draw particular attention to the hard case of the students whose patriotism led them to enlist early in the war and who are still serving. As has been feelingly expressed in our correspondence columns, the date of qualification of these young men is deferred thereby in proportion to their length of service; their fellow students who did not enlist enter on the race of life with a proportionately long start; while their parents, who must support them until they become qualified, are heavily handicapped.

What, then, are the measures that should be adopted to minimize the future evils that will surely result from the present shortage of medical students? These are clearly indicated by the Committee of Reference and the Central Medical War Committee, and strong representations have been forwarded by both bodies to the responsible authorities. The main steps advised are three in number. In the first place all medical students now serving in the army who have already passed their examinations in physiology and anatomy should be demobilized and returned to

¹ SUPPLEMENT, September 15th and 22nd, 1917, pp. 57 and 62.

² Ibid., March 3rd, 1917, p. 42.

³ Ibid., December 2nd, 1916, p. 149.

⁴ BRITISH MEDICAL JOURNAL, 1915, ii, p. 785.

the medical schools to complete their studies. In the second place, medical students now serving in the army who have not yet passed these examinations should be seconded to their medical schools for a reasonable period to enable them to pass them, and, if successful, should be demobilized to complete their professional education. In the third place, the calling up of bona fide medical students who have completed their first year of study should cease. Again, in the opinion of those well qualified to judge, senior medical students serving as surgeon probationers in the navy should be demobilized and returned to their medical studies after six months' service afloat.

The whole question is one of the greatest moment, for it is obvious that if we are face to face with a shortage of doctors at home and abroad now, as is notoriously the case, in the near future this shortage will become much more serious. And as the medical schools begin their new session next week, it is important that an early decision on the points indicated above should be reached by the authorities concerned.

URINARY SPIROCHAETOSIS.

THE present war, had it been remarkable for nothing else, would have gone down to history as a disease-begetter. The number of new diseases, real and imaginary, which have been born amidst the blood of the battlefield and the mud of the trenches is already great, and shows promise of being increased. Trench fever, trench feet, trench nephritis, all carry part of their etiology in their name. The committee appointed by the Royal College of Physicians, when it sanctioned the inclusion of the term "pyrexia of uncertain origin" in the nomenclature of diseases, could little have foreseen the gratitude felt by hard-pressed medical officers in the field towards the inventor of "the diagnosis P.U.O." For the demand of the official card indexer for a label of some sort is especially troublesome in connexion with that rather large class of febrile conditions which present neither a diagnostic temperature chart nor an unmistakable symptom complex. It may have been thought at first that this apparent failure to arrive at a concrete diagnosis was due to lack of skill or experience on the part of those who were engaging in unusual medical work under particularly unusual circumstances. The advent of the travelling field laboratory with its expert advice must have been most helpful in many of these cases of pyrexia of obscure origin, particularly in sorting out with greater precision the typhoid-dysentery group of diseases; but even here new conditions brought new difficulties in their train.

The pyrogenic bacteria having been accounted for to some extent, there was opportunity for the concentration of attention on those other recognized classes of fever-producing organisms, the pathogenic protozoa and their possible allies, the chlamydozoa. The malarias, the relapsing or recurrent fevers, and various others have been definitely associated with protozoal infection. Of most interest, perhaps, is that somewhat indefinite group of recurrent fevers with which in several instances spirochaetal or spirillar forms have been identified and which are for the most part insect-borne or tick-borne infections.

The more or less recent work on haemorrhagic jaundice has demonstrated the intimate relationship of that disease to spirochaetal infection, a fact which is referred to by Lieutenant Stoddard and by Major Patterson in communications published elsewhere in this issue of the JOURNAL. Moreover, it has brought

to light the interesting fact that in such diseases the kidney is a chief site of infection, and that in consequence evidence of infection may be confidently looked for in the urine. It is impossible at present to estimate the importance of this far-reaching observation, but it seems clear that we now have at our command a diagnostic method of the greatest utility which must in effect become a fairly trustworthy means of assorting a hitherto heterogeneous group of pyrexial diseases. Apart from the satisfaction which clinical pathologists must feel in the possession of a new and, by this time, approved instrument of diagnosis, there is a much more important gain to our general pathological knowledge. It may well be said that etiology is the only true and permanent foundation of all medical knowledge and practice. Empiricism and symptomatology will doubtless serve many men for everyday work, but the true basis of scientific medicine and practice is a full comprehension of the actual factors at work in the causation of disease, and not the least important of these factors is the causal agent, primary or secondary, as the case may be.

All urinary spirochaetes, however, are not necessarily pathogenic. This troublesome fact will doubtless be received by pathologists with their usual calm resignation, and will only incite them to further effort directed towards the absolute identification and specification of the pathogenic varieties or the pathogenic phases. There exists little doubt, there is in fact some considerable evidence, that spirochaetes and allied forms have a definite life-history marked by more or less characteristic morphological changes. It is many years now since the researches of the Egyptian workers, Balfour, Dutton, Todd, and others, brought to light the important discovery of "granule shedding" in the spirochaetes. The almost contemporaneous work of Leishman demonstrated the remarkable fact that in the intermediate host—for example, the tick, *Ornithodoros moubata*—infection was continued from one generation to another by spirochaetal granules deposited and enclosed within the eggs of the tick.

It may thus be gathered that the mere discovery and demonstration of spirochaetes in the urine of pyrexial cases does not necessarily carry us any great length in our efforts to combat the incidence of "pyrexia of uncertain origin." Nevertheless, we have some justification in surmising from analogy that the infection is insect-borne or tick-borne. Such a surmise, however, does not necessarily limit us; it merely indicates a profitable direction for further inquiry. We are glad to welcome these researches along a line of unusual technical difficulty, and it is some satisfaction to realize that even in our intense desire to "get on with the war" the importance of such investigations as an efficient means towards that end is not being lost sight of.

MOSQUITOS AND FLIES IN THE EPIDEMIOLOGY OF ACUTE POLIOMYELITIS.

THE transmission of disease by insects has been so brilliantly shown in malaria, yellow fever, trypanosomiasis, and other tropical fevers that there is some danger that its instrumentality may be assumed in other instances without exact proof. Thus flies and mosquitos have often been suspected to be responsible for the spread of acute poliomyelitis, and there is some circumstantial evidence in favour of this view—namely, the sudden disappearance of the disease with the onset of cold weather and the usual incidence of the disease in one only of several members

of a family. Rosenau and Brues, indeed, by allowing many thousands of stable flies to feed first on an infected monkey and immediately afterwards on a normal monkey, succeeded in transmitting poliomyelitis, and Anderson and Frost first confirmed and later contradicted this. Such transmission is, it appears, mechanical only, and not in the sense of an intermediate host. Noguchi and Kudo¹ have recently carried out an experimental research to determine if the mosquito *Culex pipiens*, the common house-fly, and the blue-bottle can take up the poliomyelitic virus and make it increase within their bodies. Young growing larvae of *Culex pipiens* were fed on active poliomyelitic virus and subsequently the adult mosquitos were allowed to bite a normal *Macacus* monkey. In another series of experiments female mosquitos well engorged with blood from an infected monkey were, after an interval of one to three weeks, allowed to feed on a normal monkey. Both these series of experiments were negative. Non-biting flies may, of course, mechanically convey the poliomyelitic virus just as they carry about pathogenic bacteria, but so far no experiments have been made to decide if the poliomyelitic virus can enter the fly larvae when the latter are fed on poliomyelitic material, and, if so, if it can multiply in the body cavity of the larvae. This is important, for if it occurred, flies by regurgitating and excreting food about persons or their articles of diet might spread the disease. To test this point, the larvae of house and blue-bottle flies were fed on the brain tissue of an infected monkey, and later the pupae and imagines of these larvae were made into an emulsion which was filtered and injected into the brain of a monkey without any result. These experiments, therefore, do not lend any support to the view that the disease is spread by mosquitos or non-biting flies, and Flexner's hypothesis of direct contact from one individual to another still holds the field.

DISEASES OF ANIMALS.

In his report for 1916 to the Board of Agriculture and Fisheries² Sir Stewart Stockman, the chief veterinary officer and director of veterinary research, briefly reviews the prevalence of the more important animal diseases. Owing to the exigencies of war time the scope of these reports has been narrowed to embrace little more than is needed to preserve the continuity of the series. The only exception is in the case of swine fever, which, by reason of the special nature of the work carried out, is dealt with at some length. The number of suspected outbreaks during the year was over 16,000, and of these 4,331 were confirmed by combined inquiry in the field and in the laboratory. Serum treatment for this disease was introduced in September, 1915, and was applied on a large scale and upon an organized plan throughout the following twelve months. It was combined with quarantine restrictions on infected premises throughout the whole country. During this period the serum treatment was applied in 2,100 outbreaks involving 77,900 pigs. Among these the death-rate was 34.6 per cent. During the same period 38,229 pigs were involved in outbreaks on premises upon which serum treatment was not adopted, with a death-rate of 52 per cent. In the former group the number of animals freed at the end of the outbreak amounted to 38.6, in the latter group to 14.8 per cent. These figures support the claim that serum treatment saves pig life on infected premises. Serum treatment is preventive and not curative; therefore successful results largely depend upon getting in touch with outbreaks before infection is spread far afield; it is practically valueless for pigs in the grip of infection before treatment. On the whole, the results of prophylactic serum treatment are certainly encouraging. Glanders was less prevalent during the year than in 1915, and there were less than half the number of outbreaks

which occurred in 1914. The position in London is said to be most encouraging, and calls for a special effort by local authorities to eradicate the disease finally. With regard to anthrax, the practice of attempting to save the carcasses of animals by bleeding them at the point of death, or immediately after death, and dressing them, is very severely condemned. The endeavour to save the carcasses in this way led to six human beings, who handled them, becoming infected.

A LEGEND OF SALERNO.

At the present time, when the world is at war and most things are in the melting-pot, there is little inclination and less leisure to devote to the ancient history of medicine, and yet it is a relief to turn for a short time to articles, such as Dr. Charles Singer's "A Legend of Salerno: How Constantine the African brought the Art of Medicine to the Christians,"¹ which carry the reader into the shadows of the past. The only certain facts about Constantine are that he died about 1087 and that shortly after works emanating from the school of Salerno were already borrowing from writings attributed to him, but which were for the most part poor translations from the Arabic of Isaac Judaeus (A.D. 932). Practically the only account of his life is from a very unreliable source, Peter the Deacon (1107-1140), and is to the effect that, leaving Carthage, where he was born, he spent thirty-nine years in absorbing the learning of Babylon, India, Ethiopia, and Egypt, and then returned to his native town only to find that his reputation for Gentile learning endangered his life. He therefore escaped to Salerno, and after lying hidden as a beggar for a time was recognized by the brother of the King of Babylon, honourably received by the Duke Robert, and passed to the monastery of Monte Cassino, where he became a monk and the translator of a perfect multitude of foreign works. This history is probably not much more credible than the following legend, reminiscent of the Arabian Nights, which Dr. Singer has extracted from a manuscript of 122 closely written folios, numbered Sloane 2426, in the British Museum, and dealing with anatomy, the story being interpolated in reference to the authoritative work of Avenzoar of Cordova. Among the 1,400 physicians of Cordova Avenzoar was the chief, and on being summoned by Abmansor the King when taken ill far from home, sent his favourite pupils Constantine and Ali in his place. After curing the King of a quartan fever and incidentally giving an overdose of opium, Constantine got tired of his office and, without telling his colleague, slipped off by sea, but was held as a prisoner by the sailors and sold as a slave in Salerno; here he approached the Prince, saying, "If thou wilt free me from the misery of this skin-dressing trade, I will free thee from thy sickness." The Prince, not believing him to be a physician, made him perform first on a sick prisoner. "And it was so; first the prisoner and then the Prince was cured, and cured, mind you, by God's own grace, who willed to bring us this art through the agency of Constantine."

TETHELIN FOR DRESSING WOUNDS.

THE experience of war surgery shows that in countless cases of gunshot wounds some drug that would lead to rapid repair by encouraging the growth of granulation tissue would be of the highest practical value. So often one has seen these wounds under treatment pass into an indifferent stage in which repair and cicatrization hang fire, and no progress is made for weeks or months together. Diet and environment may be altered and the changes rung on the surgical dressings applied, but the granulation tissues remain unresponsive, otiose, and the open wound fails to close. Have we any drugs to stimulate granulation tissue? Scores, if one may believe their discoverers or patentees, but experience is apt to answer—None.

¹ Hideyo Noguchi and Rokusaburo Kudo, *Journ. Exper. Med.*, Baltimore, 1917, xxvi, 49-57.

² H.M. Stationery Office. 1917. Price 2d.

¹ C. Singer, *Johns Hopkins Hosp. Bull.*, Baltimore, 1917, xxviii, 64-69.

For this reason it is of great interest to read¹ that tethelin, a substance extracted from the anterior lobe of the pituitary body, has a remarkable influence in accelerating the growth not only of the Flexner-Jobling transplantable carcinoma of rats but also of the granulation tissue in superficial wounds in mice. Tethelin is described as a hygroscopic and unstable substance, soluble in water and in alcohol, ether, and carbon tetrachloride. Its chemical composition is obscure, but it breaks down on hydrolysis, yielding unsaturated fatty acid soaps and inositol, and it is said to contain an imine-azoyl group. Administered by the mouth to young mice it retards growth, but accelerates growth in the adult animals and makes their coats silky. It accelerates, too, the regaining of weight in mice that have been starved for twenty-four hours; the subcutaneous injection of tethelin was found to exert a stimulating influence on the processes of tissue repair for at least thirty-six hours. Dr. Robertson also found that it greatly accelerated the repair of the wounds caused by punching out (under ether anaesthesia) discs of skin from the sides or flanks of mice. In the animals treated with tethelin the wounds were contracted and filled with white cicatricial tissue at the end of six days, at a time when in the control animals the wounds were still filled with granulations, and had only begun to contract. It is argued that these hypodermic injections exerted a remarkably stimulating effect on the repair and replacement of lost tissue in these experiments. What is true of mice may well be true of men, and we understand that tethelin is now being given a trial as a local and as an internal application in the treatment of men with callous wounds in this country. We wish it all success; the pharmacopoeia certainly stands in great need of a drug possessing the powers ascribed to tethelin. It may be added that the name "tethelin" is derived from the Greek word *τεθλῶς*, a perfect participle used by Homer in a present sense, and meaning "growing" or "luxuriant."

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.²

THE present part, a double one, of the *New (or Oxford) English Dictionary* contains a large number of medical terms or of terms which may be used in a medical sense. Extending, as it does, from *Verificatory* to *Visor*, it includes all the words derived from *vermis* (a worm), such as *vermicide*, *vermicular*, *vermiform*, *vermifuge*, *verminate*, *vermiparous*, etc.; all those coming from *verruca*, from *vertebra*, from *vesica*, from *vesicle*, from *villus*, from *virus*, and from *viscera*, as well as a number of single words of considerable interest, such as *vertigo*, *vesania*, *verumontanum*, *vestibulitis*, *vestibulotomy*, *vestigial*, *viable*, *vibex*, *vibrio*, *vicitiation*, *vidian*, *violuric*, *viripotent*, etc. It would be absurd to expect the *Dictionary* to give all the multitude of proprietary medicines; but since *veronal*, the hypnotic, is named and illustrated, it would have made the reference complete if *barbitone*, the official drug corresponding to it, had been introduced into one of the quotations. It is, however, a high compliment to the accuracy and compendiousness of the *Dictionary* that one has to search for criticism in so comparatively slight an omission. *Verruga* is one of the relatively few terms which have come into English via Spanish; it is a febrile disease endemic in Peru (hence also called Peruvian wart), and characterized by warty eruptions or tumours of the skin; its first use in English dates from 1883 (in Fagge's *Medicine*). *Verruga* is of course, simply the

Spanish form of the Latin *verruca*, a wart. *Verniz* (varnish) is classified as "obsolete, rare"; but surely *vernix caseosa* is frequent in midwifery textbooks, if not elsewhere. The editor is wise in defining *viable* and *viability* in general terms, for in the present fluid condition of medical and perhaps also of legal opinion he would have found it difficult to state any exact number of weeks or days for its establishment, electrical incubators, and other devices constantly tending to throw the date of viability backward towards conception. It is an interesting fact that there are two "viables," the one which has just been referred to, from the French *vie*, life, and the other meaning traversable, from the Latin *via*, a way. As has often been pointed out in connexion with earlier parts of the *Dictionary*, the medical meanings of ordinary, non-medical words are always extremely well done and fully illustrated. This is clearly shown by a reference to such terms as *vernal*, *version*, *vessel*, *veterate*, *vicarious*, *vicious*, *vigil*, *violation*, and *virtue*. *Vex*, one had almost forgotten, used to mean to afflict physically, to affect with pain or suffering; it is now so employed only in poetry. Probably few know that *visit* has or had three medical meanings: the first is the ordinary one—a professional call made by a doctor on a patient; the second is rare—the surgical examination of a wound; and the third is obsolete—an occurrence of menstruation. The verb has yet another meaning—namely, to be visited by a disease or sickness. "When a house hath the plague, we use to say, Such a house is visited" is a quotation of the year 1645 (Caryl).

RICHARD WISEMAN AS A NAVAL SURGEON.

RICHARD WISEMAN, sergeant surgeon to Charles II and author of treatises that can still be read with pleasure for their racy English and the strong common sense of their teaching, served as an army doctor in the Civil War, but he began his career as a naval surgeon, and Longmore¹ thinks it probable that his apprenticeship began at sea. He does not seem to have served in British ships, but was first in the Dutch and much later in the Spanish navy. Wiseman's first publication, dated 1672, was written especially for the "Sea Chirurgeons who seldom trouble their cabbins with many books." He mentions that his knowledge and experience as an English "artist in chirurgy" had been gained by practice on board ship no less than on shore. Wiseman was a conservative surgeon and condemned indiscriminate amputation: "Amongst the Cruisers in private Fregats from *Dunkirk* it was complained, that their Chirurgeons were too active in amputating those fractured Members. As in truth there are such silly Brothers, who will brag of the many they have dismembred, and think that way to lie themselves into credit. But they that truly understand Amputation and their Trade, well know how villanous a thing it is to glory in such a work." Elsewhere he says: "Consider well the Member, and if you have no probable hope of Sanation, cut it off quickly, while the Souldier is heated and in mettle. But if there be hopes of Cure, proceed rationally to a right and methodical Healing of such Wounds; it being more for your Credit to save one Member than to cut off many." He did not hesitate to amputate when there was no hope of saving the wounded limb, but he insists that the operation "must be done in its proper time, that is to say, suddenly upon the receipt of the Wound, before the Patient's Spirits be overheated either with Pain, Fever, &c." He mentions that "in the Armado Naval of *Dunkirk*" the surgeons "after every Fight went together visiting one another's wounded men." Wiseman always tells frankly of his failures, and he confesses that once regard for his own safety led him to abandon a man who in the heat of fight was put down into the hold with a badly shattered arm. "I ought," says Wiseman, "to have cut off this man's arm presently; but a sudden cry that our ship was

¹ Richard Wiseman. London, 1891.

on fire put me in such disorder that I rather thought of saving myself than dressing my patients. I hastily clapped a dressing upon the wound and rolled it up, leaving his arm in his other hand to support it, and endeavoured to get up out of the hold as others did, verily believing I should never dress him or any of them more." The fire, however, was got under, and when the fight was over and they had got into the next port, Wiseman was able to treat the man successfully. He adds, with a little touch of malice: "When it came to my turn to be visited by my Brother Chirurgeons of our Squadron, they did not dislike the Wound, nor my way of dressing; but they laugh at the excuse I made for not cutting off his arm, and doubted I should yet be forced to do it." The patient, however, eventually recovered without the loss of his arm. Wiseman speaks of his service with the Dutch as having been of long duration, and of his having been in many engagements, but he gives no dates. He served about three years in the Spanish navy, probably between 1656 and 1660. Whilst Wiseman served among the Dunkirkers, "where *Snick and Snee* was as it were a fashion," he had much experience of wounds of the face. The following incident may be quoted as an example of the dramatic way in which he tells a story. Whilst his ship was riding at anchor in the Groine, some Hollanders from Hamburg came in with three ships for the King of Spain. The men were drinking together on shore when one of the Hollanders, a boatswain, "began to prate of religion, and upbraided one of the Dunkirkers for wearing a cross. In a little while, growing more heated from the effects of his potations, he became quarrelsome. After frequent repetition, with curses, that 'he would not wear a Cross, no, the Devill take him,' one of our men beat him down, and fell with him, then, kneeling upon his breast, and holding his Head down, he drew out a knife sticking in his Sash and cut him from the ear down towards the Mouth, then from under the Eye from that Check-bone to the nether Jaw. 'Now,' said he, '*you shall wear a Cross, that the Devill do not carry you away.*'" Wiseman was a man of somewhat poor physique, with a tendency to pulmonary trouble, of which he finally died. One of his case records mentions that the patient whom he had "lately dismembered" ran away on an alarm that the fort was taken, and that, doubtless owing to shortness of breath, he was unable to keep up with the fugitive. He was liable to attacks of haemoptysis from the time he returned to London after his service in the Spanish navy. It is to the breakdown in his health in his latter years that we owe Wiseman's great work *The Chirurgical Treatises*. He died on August 29th, 1676; the date of his birth is uncertain, but it was probably between 1620 and 1623.

PROTECTIVE INOCULATION AGAINST BACILLUS WELCHII.

FROM an investigation conducted on five strains of *Bacillus welchii*, four of which were obtained from the Western front in France, Bull and Pritchett¹ have arrived at a conception of the pathogenic action of the organism totally different from any previous view. It is true that in the past the general symptoms were ascribed to an intoxication, but this was regarded as due either to decomposition products of the infected tissues or to ordinary endotoxin absorption. K. Taylor explained the locally destructive effects of the bacilli as the mechanical result of the gas, which by pressure on the blood vessels sets up necrosis; and Sir A. E. Wright believes that acidosis occurs and by diminishing antitrypsin leads to tryptic digestion of the proteins, thus providing a highly suitable medium for bacterial growth which becomes explosive and is followed by acidæmia. Bull and Pritchett show that the infective

processes induced in rabbits, guinea-pigs, and pigeons are local, and that few bacilli enter the general circulation during life or immediately after death; and that the general symptoms are due to an exotoxin which is a complex of a haemolysin and another poison acting locally on the tissues and blood vessels, thus causing oedema and necrosis, and probably exerting a general toxic effect in addition. Thus the filtrate of a culture, if injected intravenously, causes rapid death from massive destruction of the red blood corpuscles, acid intoxication and agglutinative bacterial emboli being excluded as lethal factors. Successive injection of carefully graded doses of this toxic filtrate into pigeons and rabbits gives rise to active immunity, and the blood from the immunized rabbits neutralizes the toxic filtrate both *in vitro* and *in vivo*, and is further both protective and curative against infection with the spore and the vegetative stages of *Bacillus welchii* in pigeons.

THE MEDICAL SOCIETY OF LONDON.

THIS society has issued an attractive programme for the coming winter session. The opening meeting will be held in the house of the society, 11, Chandos Street, Cavendish Square, on the evening of Monday, October 8th. The annual meeting will be held at 8 o'clock. At 8.30 the in-coming president, Sir St. Clair Thomson, will deliver his inaugural address. He has selected as his subject a sketch of the interesting personality of Dr. Lettsom, the founder of the society. This will be followed by two communications by Dr. Hutchison and Dr. Sparks on a matter which the French would call of "lively actuality"—namely, "War bread and its effects," a subject of universal, personal, and national interest. During the session discussions will be held on modern artificial limbs, and their influence upon methods of amputation; the value and limitations of sanatorium treatment for tuberculosis; facial surgery, and anaesthetics in war surgery.

SIR ROBERT W. PHILIP has been unanimously elected by the Edinburgh University Court to the chair of tuberculosis, which has just been created in the university. This is the first professorship of tuberculosis to be founded in the United Kingdom.

At a meeting of the War Emergency Fund of the Royal Medical Benevolent Fund, held in London on July 31st, 1917, it was decided to hold a general meeting of the medical profession in October in order to nominate a representative General Committee, and to discuss the best methods of promoting this appeal. This meeting will be held on Wednesday, October 10th, at the Medical Society's Rooms, 11, Chandos Street, Cavendish Square, W.1, at 5 p.m. It is hoped that the meeting will be largely attended, in order that the appeal may be well supported and made widely known to the profession and the public.

THE second American Congress of Children's Diseases is to be held at Monte Video under the presidency of Dr. Luis Morquio, a leading specialist in Uruguay. The first meeting of the congress took place five years ago at Buenos Aires.

THE committee appointed under the will of the late Mr. Leopold Salomons for the distribution of his residuary estate, announces the allocation of a further £50,000 to hospitals. The grants include £7,000 to the London Hospital, £2,000 each to Middlesex, Guy's, King's College, University College, Royal Free, St. Bartholomew's, St. George's, St. Mary's, St. Thomas's, and Westminster Hospitals; and £1,000 each to Charing Cross, Seamen's (Greenwich), Great Northern, West London, Cancer, Brompton, National Hospital for the Paralysed, Children's (Great Ormond Street), Royal Surrey County (Guildford), and Lock Hospitals.

THE WAR.

THE GENEVA RED CROSS CONFERENCE.

A CONFERENCE of European neutral Red Cross societies was held last week at Geneva under the auspices of the International Committee of the Red Cross. The main subject for discussion was the improvements which could be introduced at the beginning of the fourth winter of the war into the conditions of life of prisoners of war, of interned or deported civilians, and of the inhabitants of occupied countries. Delegates were present from the Red Cross societies of Denmark, Holland, Norway, Sweden, Spain, and Switzerland. The principal resolutions adopted by the conference were to the following effect:

That where neutral Red Cross societies cannot exercise effective surveillance the neutral Governments representing belligerents should have at the embassies or legations delegates authorized to visit prisoners everywhere, particularly in camps and dockyards within the armed zones. In this matter reciprocity between belligerents should be complete.

That the visits of medical commissioners for the selection of candidates for repatriation should be more frequent.

That measures of reprisals against prisoners of war should be renounced by the belligerent Governments, or only taken after four weeks' notice, this period to be employed by a neutral commission in checking the motives alleged for the proposed reprisals.

That the American Red Cross Society should be urged to secure the dispatch of provisions to prisoners of war belonging to the Entente countries; and that the distribution of provisions and of every kind of aid should be assured through the medium of the delegates of the neutral Red Cross.

That the belligerent Governments should be urged to obtain the early realization of a scheme for the repatriation of unwounded prisoners who have endured long captivity, on condition that they are not sent back to the front; the exchange of entire categories being preferable to a system of individual exchanges.

That all interned civilians should be repatriated as promptly as possible, and wherever this cannot be carried out immediately the fate of civilian prisoners should be ameliorated.

That belligerent Governments should authorize imports and exports from neutral countries of sanitary products needed for the care of the sick and wounded.

The full text of the various resolutions is being forwarded to the various Red Cross societies and Governments.

PARCELS FOR OFFICER PRISONERS OF WAR.

A MEMORANDUM describing the revised scheme for the forwarding of parcels to officer prisoners of war has been issued by the Central Prisoners of War Committee, which is the care committee for all officer prisoners. The right to send parcels to an officer prisoner rests with the next of kin, but may be transferred by the latter, or by the officer himself, to any person. Parcels may be dispatched by the Central Prisoners of War Committee itself, by any authorized association, by a shop, or privately. Not more than 100 lb. of foodstuff may be sent to any officer prisoner during each four weeks. The control of the total amount sent in any period and the arrangements for censorship are provided for by a system of coupons issued by the Central Prisoners of War Committee in booklets. A small quantity of medical comforts and drugs other than those in the War Office prohibited list may be sent by the Invalid Comforts Fund, 19, Second Avenue, Hove, on application to the Fund, but only through that channel. The prohibited drugs are:

Emetine, strychnine, thymol, caffeine, capsicum, cascara, glycerin, ipecacuanha, olive oil, lanoline, quillaia bark, nuxvomica, senna, balsams, resins, oleo resins, gums, vaseline, aspirin, antipyrin, pyramidon.

The Army Council have decided that officers' parcels should be brought under control only in so far as they contain foodstuffs, medical comforts, drugs, and wines. Other articles, such as tobacco, cigarettes, and clothing, may, if not on the prohibited list, be sent through the parcel post in the ordinary way, and not under cover of the Red Cross label; they will pass through the ordinary

censorship. A special scheme has been drawn up for officer prisoners interned in Bulgaria and Turkey. The address of the Central Prisoners of War Committee is 4, Thurlow Place, London, S.W.7. The excellent work of the Officer Prisoners of War Fund will be transferred to 104, Brompton Road, S.W.1, on October 1st.

HONOURS.

A SUPPLEMENT to the *London Gazette*, issued on September 21st, contained a dispatch from Vice-Admiral Sir Rosslyn E. Wemyss, K.C.B., late Commander-in-Chief, East Indies Station, covering a report by Captain Wilfrid Nunn, C.M.G., R.N., on the operations of H.M. gunboats in Mesopotamia from December, 1916, to March, 1917. Appended to the dispatch is a list of officers for special promotion, honours, or awards, which includes the following medical officers:

Temporary Surgeon Robert G. Elwell, R.N. (H.M.S. *Gadfly*).
Has rendered valuable service under fire on many occasions.

Surgeon Frederick G. E. Hill, R.N. (H.M.S. *Moth*).

Who, finding a man wounded on the battery deck, gallantly, under heavy fire, carried him into the sick bay to dress his wounds. Whilst doing this the man received another wound through his throat, and Surgeon Hill himself received a nasty wound in his forearm. Nevertheless, although in considerable pain and until his arm became too stiff to use it, he proceeded to dress and attend to all the wounded on board.

Surgeon J. C. Kelly, R.N. (H.M.S. *Tarantula*).

Attended to wounded whilst fire was at its hottest in an exposed position.

Surgeon James P. Shorten, R.N. (H.M.S. *Mantis*).

Continued to dress and attend to the wounded in the open while under very heavy fire.

In recognition of their services the King has appointed Surgeon F. G. E. Hill to be a Companion of the Distinguished Service Order, and the other three medical officers receive the Distinguished Service Cross.

Staff Surgeon T. W. Jeffery, R.N., H.M.S. *Proserpine*, and Staff Surgeon G. G. Vickery, H.M.S. *Dalhousie*, are among the officers recommended for good services at the base which largely contributed to the successful operations.

MENTIONED IN DISPATCHES.

East Africa.

A special supplement to the *London Gazette*, issued on September 22nd, contains a list of officers brought to the notice of the Secretary of State for War by Lieut.-General A. R. Hoskins, D.S.O., Commander-in-Chief East African Field Force, for distinguished service in the field. The following medical officers are included in the list: Lieut.-Colonels R. L. Girwood, M.B., S.A.M.C., and H. W. Vaughan-Williams, M.B., S.A.M.C.; Temporary Lieut.-Colonel A. D. Milne, M.B., East African Medical Service; and Major E. T. Harris, M.B., I.M.S.

Nyasaland.

In Brigadier-General Northey's dispatch on the operations in the Nyasaland Protectorate, transmitted to the Colonial Office by the Governor of Nyasaland and published as a supplement to the *London Gazette* of September 25th, the following medical officers are mentioned: Major D. M. MacGregor, S.A.M.C.; Temporary Major H. S. Stannus, M.D.; Captain (temporary Major) W. F. L. A. Holcroft, M.B., S.A.M.C.; Surgeon-Captains: J. W. Bouwer, S.A.M.C., R. Bury (Nyasaland Field Force), R. R. Murray, W. J. Sheehan, E. Storrs, A. F. Wallace, and R. S. White of the Northern Rhodesia Medical Service; Captains A. P. M. Anderson and R. L. Lloyd, S.A.M.C., A. W. Forrester, Rhodesian Medical Service, M. G. Sanderson, Nyasaland Field Force; Temporary Lieutenant P. A. Lister-Smith, Nyasaland Field Force.

FOREIGN HONOURS.

Surgeon-General Sir Alfred Keogh, G.C.B., Director-General Army Medical Service, has been appointed by the President of the French Republic to be a Grand Officer of the Legion of Honour, in recognition of distinguished services rendered during the course of the campaign.

A supplement to the *London Gazette*, issued on September 24th, contains a further list of decorations awarded by the King of the Belgians to members of the British forces for services rendered during the course of the campaign; the list includes the following medical officers:

Order of the Crown.

Grand Officer: Surgeon-General Sir A. Keogh, G.C.B., M.D., F.R.C.P., Director-General Army Medical Service.

Commander: Surgeon-General Sir W. Donovan, K.C.B., Maritime Transport; Surgeon-General Sir T. P. Woodhouse, K.C.M.G., C.B., A.M.S.

Officer: Lieut.-Colonel (temporary Colonel) H. P. W. Barrow, C.M.G., A.M.S.; Colonel J. B. Wilson, C.M.G., M.D.

Order of Leopold.

Officer: Temporary Colonel J. D. Alexander, D.S.O., M.B., R.A.M.C.

Chevalier: Captain T. F. Corkill, M.C., R.A.M.C. (S.R.); Temporary Captain J. H. H. Pearson, M.D., R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed in Action.

SURGEON PROBATIONER H. A. POTTER, R.N.V.R.

Surgeon Probationer Herbert Alfred Potter, R.N.V.R., was killed in action on September 19th, aged 21. He was the only son of Mr. Alfred Potter, of Hatfield Broad Oak.

ARMY.

Killed in Action.

CAPTAIN B. A. BULL, R.A.M.C.

Captain Benjamin Allen Bull, R.A.M.C., was killed in action on September 16th. He was the only son of Professor Bull, of Chorlton-cum-Hardy, Manchester, and was educated at Oxford and at St. Bartholomew's Hospital, taking the diploma of L.M.S.S.A. in 1915. He took a temporary commission in the R.A.M.C. last year, and was promoted to Captain after a year's service.

CAPTAIN H. D. ECCLES, R.A.M.C.

Captain Horace Dorset Eccles, R.A.M.C., was reported as killed in action, in the casualty list published on August 28th. He was educated at Guy's Hospital, took the M.R.C.S. and L.R.C.P.Lond. in 1893, and after acting as clinical assistant at Guy's, went out to New Zealand, where he was in practice at Kawa Kawa, Bay of Islands, till he joined the army.

LIEUTENANT A. G. DUNN, R.A.M.C.

Lieutenant Arthur Gibson Dunn, R.A.M.C., was reported as killed in action, in the casualty list published on September 19th. He was educated at Newcastle-on-Tyne medical school, where he gained the Gibb and the Goyder scholarships, and graduated M.B., B.S.Durh. in 1903, also taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1906, and the M.D. Durh. in 1915. After filling the posts of house-surgeon, accident house-surgeon, and ophthalmic house-surgeon at the Royal Infirmary, and of resident medical officer of the dispensary at Newcastle, he went into practice in that city, where he held the appointment of refractionist in the eye department of the Royal Victoria Infirmary. He had only recently joined the R.A.M.C.

Died on Service.

LIEUTENANT D. ANDERSON, R.A.M.C.

Lieutenant David Anderson, R.A.M.C., died in a French hospital on September 13th, aged 31. He was the eldest son of Mr. A. Anderson of Cambuslang, and was educated at Glasgow University, where he graduated M.B. and Ch.B. in 1908, afterwards going into practice at Washington, County Durham. He had only recently taken a temporary commission in the R.A.M.C.

LIEUT.-COLONEL E. H. OPENSHAW.

The *Pioneer Mail* of August 11th announces the death at the front, presumably in Mesopotamia, of Lieut.-Colonel Edward Hyde Openshaw, of Prince Albert's Somerset Light Infantry. He was educated at the Bristol Medical School, took the M.R.C.S. and L.R.C.P.Lond. in 1890, and after acting as house-surgeon of the Bristol Eye Hospital went into practice at Cheddar, in Somersetshire. Before the war he held the rank of Major in the 4th (Territorial) Battalion of his regiment, and was a member of the Territorial Force Association for Somersetshire. Last year he succeeded to the command of his battalion, which had recently been stationed at Wellington, in Southern India.

Wounded.

Lieut.-Colonel H. Gibson, R.A.M.C.

Major J. H. Dixon, R.A.M.C. (T.F.).

Captain F. F. Dunham, Canadian A.M.C.

Captain A. Gaston, R.A.M.C. (temporary).

Captain J. Lyons, R.A.M.C. (temporary).

Captain H. Moore, M.C., R.A.M.C. (temporary).

Captain A. Morris, R.A.M.C. (T.F.).

Captain B. N. Murphy, M.C., R.A.M.C. (temporary).

Captain C. H. L. Nixon, R.A.M.C. (temporary).

Captain J. F. W. Sandison, R.A.M.C. (S.R.).

Captain D. E. Scott, R.A.M.C. (temporary).

Captain T. M. J. Stewart, R.A.M.C. (temporary).

Lieutenant and Quartermaster E. F. Masters, R.A.M.C. (T.F.).

Sister W. Hawkins, T.F.N.S.

DEATHS AMONG SONS OF MEDICAL MEN.

Bracey, Victor Charles Edelsten, 2nd Lieutenant R.F.C., killed while flying in Hampshire on September 23rd, aged 19. He was the only son of Dr. W. Edelsten Bracey, honorary Lieutenant R.A.M.C., of Wedmore, Somerset, and was educated at Blundell's School. He obtained his commission in February last, and his "wings" last July. At the time of his death he was acting as an instructor.

Butcher, W. G. Deane, Captain London Regiment, killed in action on August 16th, youngest son of Dr. W. Deane Butcher, of Ealing. At Eton he won the Newcastle in 1910. He was an open scholar of Trinity College, Cambridge, and won the Craven and took a first class in the Classical Tripos in 1913. He was reported missing on August 16th, and is now unofficially reported killed in action that day.

Harrison, Major Rowland Damer, D.S.O., R.F.A., only son of Colonel Damer Harrison, R.A.M.C. (T.), of 53, Rodney Street, Liverpool, was killed on September 16th, aged 36. He had had eighteen years' service in the regular army, and before the war had served in the Royal Horse Artillery. He went to France early in August, 1914, as captain in command of an ammunition column of the R.F.A., and was present at the battle of Mons, the retreat from Mons, the battles of the Marne, the Aisne, the first battle of Ypres, the battle of Loos, and subsequent actions. Twelve months ago he was awarded the D.S.O. on the field for conspicuous gallantry in action, and was subsequently mentioned in dispatches more than once. He leaves a widow and two young children.

Jefferson, Ingleby S., Lieutenant R.N., killed by the sinking of a submarine under his command while in action in the North Sea on July 22nd, aged 24. He was the elder son of Dr. W. D. Jefferson, M.O.H., Ripon, and was educated at Aysgarth School, H.M.S. Conway, whence he passed out first, and Dartmouth. He was promoted lieutenant R.N. in 1915. He was a good all-round athlete and played for the navy in the annual football match against the army in 1914. He held the medal of the Royal Humane Society for saving a soldier from drowning.

Stephenson, Arthur Frederick Vere, Lieutenant Gordon Highlanders, younger surviving son of Emeritus Professor William Stephenson, M.D., LL.D., of Aberdeen, reported missing at High Wood, on the Somme, on July 23rd, 1916, now reported to have died of wounds as a prisoner, aged 33.

Von Winckler, Myles William, Lieutenant Middlesex Regiment, only son of Dr. William J. Von Winckler, British Guiana Medical Service, killed August 1st. He was born in Demerara, in 1893, educated at St. Paul's School, where he was in the eleven, and at Wadham College, Oxford, and joined the army through Sandhurst.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

NOTES.

SIR WILLIAM COLLINS, M.P., M.D., through the liberality of friends, has lately dispatched to the Italian and Belgian frontiers two motor ambulances equipped as mobile operating theatres according to his own design. A third ambulance of the same pattern has also been presented for use with the Greek army.

THE RED CROSS EMBLEM.

In order to prevent the improper use of the Red Cross emblem on privately owned motor cars and other vehicles, it is announced that owners of all vehicles desiring to obtain permission to display the emblem must apply through the head quarters of the command in which their cars are employed. Application will be forwarded to the War Office, and the necessary permit issued only when a car fulfils the following conditions: (1) That it is used solely for the conveyance of sick and wounded soldiers; (2) that it has been placed at the disposal of the military authorities for this purpose.

THE War Council of the American Red Cross has established a Bureau of Sanitary Service. An appropriation of £160,000 has been made for the purpose. The bureau will supervise and help in efforts to make health conditions about the camps of mobilized troops as nearly perfect as possible. A radius of from fifteen to sixty square miles will be policed for the protection of the health of the men. Increased provision will be made for milk inspection, and vigorous war will be made on malaria-carrying mosquitos.

A NATIONAL institute of malariology is about to be established in Italy; it will be a part of the department of agriculture. Its objects are to investigate the relations between malaria and agriculture; to study experimentally and otherwise the direct and indirect causes of the unhealthiness of malarial districts; and to organize and direct a campaign against those causes, and particularly against the *Anopheles*.

Ireland.

IRELAND'S MILK SUPPLY.

A MEMBER of the Local Government Board recently stated that the Board was doing all it could in order that there should be no scarcity of milk, and that it should be supplied from the country, where it was plentiful, to cities and other urban areas where it was most needed for nursing mothers and children. A circular letter was issued by the Board in May last and July to county, borough, urban, and rural councils, drawing their attention to the present milk shortage and also to the injurious effects likely to result therefrom to the health of mothers and young children. The Local Government Board points out that it is open to every sanitary authority, with the Board's approval, to make arrangements for the supply of milk to expectant and nursing mothers and children under 5 years of age, and the Board is satisfied that, if effect is given to this provision of the law, it would go far to relieve the present and prospective shortage in particular localities, provided that arrangements be made to obtain milk from places where sufficient supplies are available over and above the quantities needed for their own requirements. Care should, however, be taken not to interfere with the ordinary milk supply of the urban and rural areas, but to obtain further supplies from farmers who produce milk for the purpose of making butter or from creamery societies. The Board has been in communication with the secretary of the Irish Agricultural Organization Society with a view to the formation of a scheme for the supply of milk to Dublin and other cities and towns in Ireland, which might have the effect of meeting the present shortage.

COUNTY HOSPITAL SURGEONS AND THE NURSING QUESTION.

At a meeting of county hospital surgeons, held last week in the Shelbourne Hotel, Dublin, with Dr. M. O'M. Knott in the chair, various matters connected with the working of county hospitals were discussed, more especially those relating to the position of nurses. The opinion was expressed that the qualification of nurses ought to be dealt with in the same way as that of medical practitioners: a curriculum should be laid down, examination tests approved, and a register of nurses set up. The meeting deprecated the idea that any self-constituted bodies or boards should be established to deal with this question, and expressed the opinion that the Local Government Board for Ireland should be the statutory authority for determining by inspection which nurses' training schools and hospitals were adequate for the purpose. It was considered that the medical licensing bodies would be the most suitable for supervising examinations, and for arranging the course of study and training for nurses, with the proviso that a certain number of nurses should be called in to assist. The meeting finally decided to re-establish the County Surgeons' Association.

THE APPOINTMENT OF A DISPENSARY DOCTOR.

The Local Government Board, in refusing to sanction the appointment of Dr. R. Hayes, by the South Dublin board of guardians, as district dispensary medical officer, stated that Dr. Hayes had been sentenced by court-martial to twenty years' penal servitude for having taken part in the Sinn Féin rebellion, that he had been released unconditionally on the occasion of the general amnesty, but that he had not received a free pardon from the Crown, and added that, having regard to these facts, the Local Government Board deemed Dr. Hayes unfit to hold an appointment in the dispensary medical service. The board of guardians resolved that a request should be sent to the Local Government Board to furnish (1) a reference to the statute conferring on it the right to refuse sanction to the appointment of a dispensary doctor, and describing disqualifications; (2) a copy of the record and sentence affecting Dr. Hayes; (3) a statement as to whether the conviction and sentence referred to were those by the secret field courts-martial held in May, 1916; (4) a copy of the record on which the Local Government Board declared that a prisoner so sentenced could be released without His Majesty's pardon being first granted; and (5) a copy of the opinion of the Attorney-General showing that prisoners liberated by grace and favour of His

Majesty, while eligible for co-option to Local Government offices and for election to advise His Majesty in the High Court of Parliament, were disqualified from dispensing medicines and relieving the poor in Irish dispensary districts.

Scotland.

CHILD WELFARE IN EDINBURGH.

THE Edinburgh Corporation proposes, as part of its child welfare scheme, to establish a health home for weakly and ill-nourished children, particularly for those of pre-school age, although children in the early years of school life who are in poor health will also benefit under its provisions. The Public Health Committee are taking steps to secure a suitable place in the country where such children can be cared for amidst fresh air and healthy surroundings. The progress of the scheme will be watched with much interest.

ST. ANDREWS UNIVERSITY.

At the last meeting of the University Court of St. Andrews a letter was read from Professor William Carmichael McIntosh, M.D., resigning the chair of natural history after a connexion with the university as student, alumnus, and professor extending over a period of sixty-four years. The Court, in accepting Professor McIntosh's resignation, recorded their appreciation of his eminent services to science and the university. At the same meeting the Court appointed Dr. Edwin Matthew as additional examiner in medicine and clinical medicine for graduation for a period of three years, beginning January 1st, 1918. It was reported that an arrangement had been entered into with the Dundee Town Council for the investigation in the university laboratories at Dundee of pathological material sent by medical practitioners for the purpose of diagnosis.

England and Wales.

THE HEALTH OF LIVERPOOL IN 1916.

THE annual report on the health of the City of Liverpool for 1916 is less voluminous than in pre-war times, nevertheless it loses nothing in being concise and furnishes all the necessary information on the subject, which is the prime care of the medical officer of health, Dr. E. W. Hope. The population of Liverpool was estimated at mid-year in 1916 to be 777,247, an increase of 4,652 on the year 1915, and the density of population is about equal to 36 per acre. The birth-rate continues to decline. In 1916 it was 26.6 per 1,000, compared with 33 per 1,000 ten years ago. On the other hand it is considerably above that for England and Wales, which is 21.6 per 1,000. Infantile mortality statistics show a satisfactory decline. In 1916 the rate was 117, against 133 in 1915 and 171 ten years ago. The general death-rate in 1916 was 17.9 per 1,000, as against 18.7 in 1915.

Zymotic diseases caused 1,699 deaths in 1916, the death-rate being 2.2 per 1,000. In the latter part of September, 1916, an outbreak of plague occurred. The infection was in all probability imported. Stringent measures were taken to localize the disease, and there were only six cases, limited to three households. Three ended fatally and were proved bacteriologically to be cases of plague. All contacts were kept under careful supervision, thorough disinfection was carried out and twenty members of the sanitary staff were inoculated with Haffkine's plague prophylactic. The result was eminently satisfactory and no further development took place. No case of small-pox occurred in the city, and two cases of typhus, both fatal, were notified, but *post-mortem* examination failed to confirm the diagnosis. Enteric fever accounted for 11 deaths as against the average number, 50, during the past ten years. Scarlet fever claimed 63 deaths out of 2,148 cases, and 62 per cent. of the deaths were of children under 5 years of age.

Measles and German measles became notifiable diseases on January 1st, 1916, and no fewer than 14,732 cases were officially reported. A much larger number received hospital treatment than in previous years. The mortality was 264, as against 438 in the preceding decennium.

Whooping-cough was responsible for 235 deaths in 1916, as compared with the average, 296, during the preceding ten years. Deaths from diphtheria amounted to 143, being above the average—namely, 112—during the past decennium. Nine cases of poliomyelitis came under the notice of the health department, and of these 4 died. Cerebro-spinal fever claimed 37 cases, with a fatal issue in 23. In spite of careful investigation the source of infection could not be discovered. Fortunately no extension of the disease occurred in the households where cases were reported. Fifteen cases of anthrax were notified, and 3 ended fatally. The majority of the patients were associated with imported hides or had to do with hair.

Ophthalmia neonatorum is under most careful supervision now, and the results in treatment are gratifying, owing to prompt medical assistance being given. The authority at St. Paul's Eye Hospital has nine beds and nine cots for the grave cases, which not only ensure systematic treatment but at the same time admit the mothers, who are enabled to nurse the infants.

With regard to tuberculosis, the number of patients examined for this disease by the tuberculosis officers in 1916 was 2,124, showing an increase of 373 of those examined in 1915. In 14.1 per cent. no sign of tuberculosis was detected. Domiciliary treatment was given to 1,191 patients, dispensary treatment to 205 patients, and institutional treatment to 429 patients. The average duration of treatment in 1,081 cases was eighteen weeks; 75.3 per cent. were discharged improved, 13 per cent. were discharged not improved, 11.6 per cent. died, and there remained under treatment on December 31st, 1916, 401 cases.

Sydney.

MEDICAL INSPECTION OF SCHOOL CHILDREN.

DR. C. S. WILLIS, the Principal Medical Officer of the Education Department, in his annual report, emphasizes the point that the work of medical inspection cannot be estimated by merely considering the number of children examined. With this must be taken into account the vast distances travelled to get to the children. In several cases a journey of over a hundred miles has to be undertaken in travelling from one school to another. Experience has shown that with the present staff the medical inspection can be conducted at each school about once every three years. The school medical service was reorganized in 1913, and the first round of medical inspection for the whole State was completed by the middle of 1916. Of 247,385 children examined, 147,079 were suffering from physical defects needing treatment; of these, only 57,310 obtained treatment. During 1916, 76,929 children were medically examined at 753 schools, the staff of the travelling hospital examining 4,011 of the total at 146 schools. During the past two years there has been a progressive fall in the percentage number of children suffering from physical defects sufficiently serious to need treatment. This fall is attributed to the effect of medical school work. Of special interest is the fact that during 1916 no fewer than 36,331 children were found to need treatment for dental defects. Of these, 17,039 were treated by the department's dentists; the work done included 13,394 treatments, 46,037 extractions, and 19,256 fillings. Dr. Willis draws attention to the large number of children who have carious teeth or filthy mouths, and urges that education of both parents and children is urgently needed. While the dentists are mending defective mouths with much assiduity, sufficient is not being done to stop the manufacture of new cases. He expresses the hope that toothbrush drill will be made compulsory in schools in the near future. A scheme has been submitted to the Minister for consideration which it is hoped will cause the children to be taught not only how to clean their teeth, but also the necessity for doing so. Dr. Willis considers that there is great need for organized treatment schemes, and that the school work of this State will never be satisfactorily accomplished until the schemes already approved or their equivalent are fully established. Owing to the opposition of the medical profession to the Government's scheme of appointing specialists as department medical officers, efforts are now being made to secure the co-operation of the metropolitan hospital staffs to deal with defects in school children requiring treatment.

CHILD WELFARE.

The Minister of Health, in the course of a statement of the work now being undertaken in the interest of the children, stated that in spite of the restriction of the finances at present, much is being done in the way of propaganda work, and every mother is being educated in regard to the welfare of herself and her infant. The Government is making strenuous efforts to cope with venereal disease, and a scheme is in operation whereby every subsidized hospital throughout the State will possess a venereal clinic. Illegitimacy, another potent factor in infant mortality, is receiving much attention, and a proposal has been made to extend the system of day nurseries, institutions which do excellent work by caring for these infants while their mothers go to work. As regards the feeding of infants, the milk supply is subjected to the most rigid inspection.

HEALTH CONGRESS.

A Health Congress was held in Sydney at the latter end of July, convened by the Health Society of New South Wales. It was attended by delegates from about thirty health societies in this State, the object being the co-ordination of effort for the promotion of the public health. Four purposes were set out for the conference: (1) The care and cure of the returned soldier and sailor. (2) The restoration to efficient citizenship of the rejected volunteer. (3) The education of the children in the schools in all branches of health instruction. (4) The teaching of hygiene in the home.

EDITH CAVELL MEMORIAL.

As a memorial to the late Nurse Edith Cavell, a beautiful home in Summer Hill, one of the near suburbs of Sydney, was recently given by the owners, Mr. and Mrs. W. E. Shaw, for a rest home for nurses. A total of £10,000 has been raised by the general public, but the committee aim at securing £15,000 as a permanent endowment fund.

Correspondence.

CEREBRO-SPINAL FEVER AND ITS TREATMENT.

SIR,—In the excellent leading article on this subject which appeared in the JOURNAL of September 22nd it was stated that "from the laboratory point of view several different strains or 'races' of the meningococcus have been recognized and differentiated by their immunological reactions; indeed, forms have been described so different from one another as to deserve the name 'subspecies.'"

Carefully guarded as this statement is, your readers might, I think, reasonably conclude—unless they had occasion thoroughly to study the subject—that the existence of different strains or races of the meningococcus has been definitely established. This is very far from being the case, because practically the only evidence at present available in support of the theory is derived from serological reactions. In consequence, from the very nature of agglutination tests, all that has been clearly established is a differential value in antigens, without any light being thrown on its biological significance.

Moreover, by an alternative theory the reputed existence of multiple strains of the meningococcus can be just as easily explained by the fact, demonstrated in the JOURNAL of September 22nd under my name, that this organism represents only one of many phases in the life-cycle of a parasitic fungus. The truth is that the theory of multiple meningococcal strains has been propounded in the absence of any control morphological studies of the life-cycle of the organism, in the belief that this cycle is one of great simplicity. I am not prepared as yet to say that the theory of multiple strains will necessarily give way now that the fact of multiple phases in the life-cycle stands revealed, though prolonged morphological study of the four "strains" in question has furnished interesting evidence in that direction, as will presently appear. None the less it would appear to be well to remember that the theory of multiple strains is still as much suspect as is the legendary danger of the *Amoeba histolytica* cyst. The question is far more

than one of academic interest only, since our one hope of successful serum-therapy in cerebro-spinal fever lies in finding the correct antigen. As I have elsewhere shown, the meningococcus, as such, represents—whatever the “strain” injected—only a saprophytic phase, and it is hardly reasonable, therefore, to look for much curative virtue from an antiserum unless this be prepared by the use of an antigen derived from the parasitic phases of the life-cycle. And this the four “strains” certainly do not provide in meningococcal form. Moreover, it is impossible to forget that the specific infectivity of Gram-negative organisms in man (so far as systemic infection is concerned) as well as their antigenic value, tends to vary inversely as the readiness with which these organisms can be cultivated, isolated, and identified in the laboratory.

The saprophytic nature of the four “strains” of the meningococcus stands self-confessed in these three respects, though the statement will not be accepted by exponents of the simple life-cycle schools, who regard the difference between parasitism and saprophytism as merely an expression of a change of milieu not accompanied by developmental change in form. In my view, however, it is just that fatal facility with which the saprophytic phases of the bacterial life-cycle can be studied in the laboratory which has in the past beguiled us into assuming that the study of bacterial function *in vitro* is alone essential, and that the study of bacterial form can be safely ignored.

It becomes, therefore, doubly necessary to determine by methods other than the serological—supposed to involve the use of one phase only—whether these alleged strains are spurious or genuine.—I am, etc.,

London, W., Sept. 22nd.

EDWARD C. HORT.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

SIR,—Dr. Bell will, I hope, pardon me if I still think that he misunderstands the arrangements for the treatment of discharged disabled men and the situation which gave rise to these arrangements; and when I say this he must not accuse me of using an improper method of controversy by merely saying that he doesn't know what he is talking about. For me merely to say this about any one would be futile; for me to say it about such men as Dr. Bell and Dr. Genge would be impertinent. I ask them to believe that the object of my last letter and of the present one is primarily not controversial, but expository, and that my only reason for supposing that I understand this matter a little better than some others do is that I have been compelled to go through the educative process of discussing at every stage the details of a not very easy subject. My former attempt to point out and to correct certain misunderstandings failed; let me try again.

Dr. Bell and others are mistaken if they suppose that these arrangements have any other origin, or have been arrived at under any other influence, than the resolutions of the last Conference of Local Medical and Panel Committees. I am challenged to quote any resolution of any conference which sanctions them. The resolutions in accordance with which we acted are too long to quote here, but they will be found as Minutes 63-68 of the Conference of October 19th, 1916. It is not, of course, contended that the details of the new arrangements are set out in these resolutions. If they had been, our task would have been simple. We should simply have had to present them to the Government with the intimation that they were our final demands, to be accepted or rejected as they stood. The resolutions are more or less general in character, but they certainly involve: (1) The withdrawal from the central insurance pool of the contributions in respect of these men; (2) the securing for the profession of an increased payment corresponding to the increased amount of attendance needed; (3) the distribution of this payment for each person on a scale and conditions to be agreed upon between the Insurance Acts Committee of the British Medical Association and the Government. (4) The opportunity for practitioners not on the present panel lists to share in these arrangements if they wished. In strict accordance with these directions the negotiations have been conducted, and the result, we think, should be regarded as eminently satisfactory, though some of the details would have been modified if we could have had everything our own way.

Dr. Bell and others are mistaken, too, if they suppose that it was no trouble to persuade the Commissioners and the Treasury that there was any case at all for asking for increased payment in respect of these men. Axiomatic as this appears to Dr. Bell and to me, it was really the first three “diplomatic steps” which I named in my last letter, and which Dr. Bell omitted in his, which were by far the hardest of all. When we put forward our case for increased payment because of increased work for the disabled men, it was said on behalf of the Government that we were asking them to take account of one part only of the effects of the war on the position of the panel doctor. There were, however, other effects that would have to be taken into account, especially (1) the effect of high wages and other consequences of the war, in improving the health of many insured persons, and (2), as regards discharged soldiers, various circumstances tending to diminish the amount of domiciliary attendance required, especially the increased facilities for institutional treatment of this class. The Government contended that the onus of proof was on us, in putting forward a claim, to show that these offsets did not outweigh the increased work for some discharged soldiers on which our claim was based. The memorandum by which we apparently convinced the Government that increased payment should be given for discharged disabled men, quite apart from any other insurance problems, was published in the BRITISH MEDICAL JOURNAL SUPPLEMENT of June 16th last. May I ask Dr. Bell to read it again? He will see from it the position in which we were, and the kind of arguments we had to meet. The second of the above contentions is, of course, important, and we have asked the Commissioners to note this and several other circumstances which may lead to under-attendance, when they judge of the results of the present experimental arrangements.

Again, Dr. Bell, Dr. Genge, and others are mistaken if they suppose that the new regulations “provide that these men shall be attended in all particulars that affect practitioners under the same regulations as those applying to temporary residents.” I repeat that they are quite different; indeed, the only connexion between the two is that the temporary resident scheme is used to determine what fee per attendance corresponds to the capitation fee for the country as a whole. This fee will not, as Dr. Genge supposes, vary in different areas. It may, in fact, having regard to past experience, be considered at present as a fixed fee which, in England at any rate, will be in the neighbourhood of 95 per cent. of the schedule of fees set out in the new regulations. All attendances, however many, will be paid for at this rate, without any deduction whatever, and *irrespective of area*.

As to Dr. Genge's important point, suggesting that the contributions in respect of these men will be taken out of a pool into which no corresponding sums have been paid, the Commissioners have assured us that the actuarial formula in accordance with which the central pool is formed has been so adjusted as to take full account of the increased disablement. It is therefore a mistake to suppose that we “shall receive proportionally less for our ordinary panel patients,” or that “practitioners not at present on the panel will be paid directly out of the pockets of panel practitioners.” As to the particular question of admitting the non-panel doctors to participate, the panel doctors' only grievance, if any, is that the non-panel men are being admitted to a share of the work and to such payment as fairly pertains to that work. Even as to this, personally I doubt whether any large number of non-panel practitioners will be found participating in these arrangements, and in any case it must be remembered that accounts will be paid, with no corresponding deduction from the pool, for thousands of men who leave the army and navy uninsured persons and for thousands of others who were uninsured when they entered the services.

May I add a few necessary sentences about the general question of the remuneration for attendance on insured persons? Drs. Gardner and Veale fail to keep this question separate from that of increased payment for discharged disabled men. It is important that they should be separated in accordance with the instructions which the Insurance Acts Committee received from the last Conference. But I agree that it is at least equally important that the question of increased remuneration for

attendance on insured persons generally should be seriously pursued. Drs. Gardner and Veale refer, not quite accurately and not very courteously, to a resolution which I moved at the last Conference, not as Chairman of the Insurance Acts Committee, but as the representative of the Panel Committee which had given notice of it. That resolution stated that we had a claim to increased remuneration, and that if we did not immediately press that claim this should be considered a contribution to the national cause and without prejudice to future action. I said very little, but the resolution evidently appealed to the Conference; and I do not think the profession does itself any harm by showing a limited forbearance, and keeping right with public opinion. But things have altered since last October. The cost of living has materially risen, and we have had another year's experience of how the present system works out. The Middlesex Panel Committee has given notice of another resolution urging that we should press for the increased payment suggested in the interim report on the future of insurance practice (SUPPLEMENT, June 30th, pp. 152-3). This resolution I hope to move or support. Dr. Gardner thinks the increase ought to be 25 per cent. The Insurance Acts Committee goes further, and thinks it should be 35 per cent. Dr. Bell tells us that about September 7th last the Gloucestershire Committee issued a circular suggesting a capitation fee of 10s.; it was exactly three months earlier (June 7th) that the Insurance Acts Committee made this suggestion, and gave its reasons for making it; and it is now waiting to see if at the forthcoming Conference and afterwards Panel Committees will unite in its support.—I am, etc.,

Stroud Green, N., Sept. 22nd.

H. B. BRACKENBURY.

SIR,—I felt at first inclined to agree to the new regulations as a temporary war-time expedient. Further consideration has led me to modify my views.

Dr. Brackenbury's statement in the SUPPLEMENT of September 22nd does not help us very much. He writes of the difficulty experienced in convincing the Insurance Commissioners that there is a case for increased remuneration for the treatment of discharged and disabled sailors and soldiers. Surely this is obvious to any person of average intelligence and unbiassed judgement.

Does Dr. Brackenbury expect us to believe that the Insurance Commissioners when in secret conclave with the Insurance Acts Committee assume, when it suits their purpose, a level of intelligence comparable with that of an anencephalic monster? We know to our cost the Machiavellian astuteness of their financial juggling when evolving methods of medical remuneration in the past! Then what can be said as to the decision to take the temporary resident scheme as a basis for our remuneration under the new regulations? My experience is that the temporary resident scheme has been practically a dead letter—most men simply refuse to be bothered with it. Therefore any data based upon its working must be erroneous.

The intense feeling which has been aroused throughout the country is, I believe, most acute on the fact that Panel Committees, and through them panel practitioners, had no opportunity of considering those regulations before they were actually enforced.

Dr. Genge's letter raises a most serious question. If his statements are substantiated, we are the victims of fraud and chicanery. In that case Dr. Bell's clarion call to action will be responded to by all practitioners who are concerned to safeguard not only their own interests but those of their absent fellows.

The conference of Panel Committees which is to be held on October 18th next should be urged to pass a resolution refusing to accept the proposed method of remuneration, and as an alternative proposing a special capitation fee of 12s. 6d. (twelve shillings and sixpence), exclusive of drugs; and, further, should proceed to appoint a special committee to negotiate with the Insurance Commissioners and see that we get it.

We are told that an increase to 10s. is to be demanded for ordinary insured persons on account of the increasing cost of living owing to the war. Therefore the suggested rate for discharged and disabled sailors and soldiers is fair and reasonable. So fair and reasonable is it that we should refuse once for all to argue the point with the Insurance Commissioners.—I am, etc.,

London, N., Sept. 23rd.

A. S. DOWNTON.

CONFERENCE OF REPRESENTATIVES OF LOCAL MEDICAL AND PANEL COMMITTEES.

SIR,—On October 18th a conference of representatives of these bodies will be called together by the British Medical Association. With your permission I would like to formulate a few proposals for the immediate serious consideration of all those in our profession who take any interest in its welfare, in the progress of medicine, in public health, and in the economic conditions relating thereto. There is no doubt whatever that unless the profession soon comes into line and ceases its internal—and possibly often justified—criticisms, it will very shortly find itself a waterlogged ship with a mutinous crew, tossed hither and thither on a stormy sea by contending forces emanating from Government departments, social workers, labour bodies, committees of reconstruction, international groupings, theorists, and faddists, no one of whom cares one farthing for medicine as a science, for the welfare of its votaries, nor for the ultimate consequence of their work, so long as they can dominate and dragoon in order that, "as soon as may be," they can obtain laudation, kudos, titles, and pensions.

I would therefore first remind all of certain facts; only in this way can a true estimate of the present situation be obtained, and a correct course hope to be steered in the immediate future.

1. About the year 1900 general practitioners found themselves dissatisfied and without any efficient organization. They did not love the British Medical Association, that being an organization moulded and run for consultants only.

2. However, the general practitioners determined to seize that Association, with its prestige and funds, and to mould its purposes to their own ends. And they did so.

3. For fifteen years now, in season and out of season, with setbacks and moves forward, in ill repute and in favour, those who came forward have consistently tried to carry into effect the policy adopted. Most of the original workers have passed away; a few are left still.

4. A new generation of general practitioners has arisen which knows not Joseph. Instead of reading up the history of the past and then refreshing the organization with new ideas, energy, and grit, two schools have come to the front; one is content to say ditto to everything done "by the Association," and keeps its eyes fixed on the individuals in power, ready to take its cue from those of pleasing personality rather than to attend to convincing arguments or sound policy; whilst the other spends its time in endeavours to belittle that organization, and tries to bring into existence other groupings of practitioners. It would almost seem that they prefer the profession to continue a mob than to become an organized body.

5. It has been noticed repeatedly that men with convictions, and who, it has been stated, represent those with convictions, which they believe to be right, attend Association, Committee, Council, Representative and Conference meetings determined to assist in putting wrong right; but when they get there their determination weakens, their convictions become suggestions, the cause they would have pushed languishes, and they return to their districts silent. Have they been converted?

What are the comments?

- (a) Unless all branches of the profession quickly unite and fall into line behind one recognized and powerful organization, ceasing to be individualists (single or in groups) they will lay themselves open to be swallowed up by sections.

- (b) There is no doubt that the British Medical Association at the moment does not meet with the approval of a large and powerful number of members of the profession. There are genuine and honest reasons existing to account for this. The organization which suited 1900 will not suit for 1920.

- (c) It is quite useless to expect the Association to return to the position it was in before 1900. To ignore it or to belittle it at home or abroad will only act as a boomerang. It will continue on its way. It will prove suicidal to think or act otherwise.

Then what are the proposals?

- (i) The general practitioners may not love the Association, but they must unite and determine to seize its prestige and funds, moulding it anew to its rightful purpose. The "contents" with the present position must be brought to recognize facts and be made willing to co-operate; otherwise they should be moved on.

(ii) The coming conference offers an opportunity for those in earnest to unite and to place on the Insurance Acts Committee fifteen representatives who can together mould the policy of the Association in one branch of medical politics which affects the very foundations of medicine and public health. It is waste of time to argue "we should nominate twenty, or thirty, or all." For the present make sure of the fifteen, and that quickly.

(iii) Having elected these fifteen then it must be seen to that they, and those who think like them, are supported through thick and thin. If any fail they must come off at the first opportunity. This is not a time when sentiment and comradeship should be allowed to influence policies.

(iv) Having tried their strength through the conference then consider the Association itself; seize its Division meetings, its Branch Councils; and next year its Council and its Representative Body. Such action is constitutional, and no one who really desires the Association to be for the profession and not for himself will do other than gladly welcome and assist such a propaganda.

Then certain questions, and I have finished.

(a) What steps are the profession in each area taking to see that the right man goes to this conference? Are the writers of complaints and the groups of malcontents doing anything?

(b) What steps are these same persons and the Panel Committees taking, by means of collaboration and correspondence, to ensure that the right men are put forward for the fifteen seats, and that the wrong ones do not slip in?

(c) Are the candidates for election men who are keen on the interests of the profession as a whole; on medicine being maintained as a science, and not degenerating to the level of a well organized fried fish shop? Are the candidates men who, when inside, will not be swayed by the powers that be, but will think out for themselves proposed policies from a broad outlook, and not from a narrow class interest? Will they maintain their position, or are they men likely to be "absorbed"?

The situation is serious. The profession cannot wait much longer. Every day more disintegrating influences are being brought to bear against it. Will it wake up?—I am, etc.,

Hove, Sussex, Sept. 22nd.

E. ROWLAND FOTHERGILL.

SIR,—On reading through the interesting "Report of Action taken by Insurance Acts Committee since 1916 Conference," I came reluctantly to the conclusion that some other body devoted solely to insurance interests must soon arise if we are to be saved from disaster. The loose sheet enclosed with the report proved that I was right. The Association, as the bulwark of the profession, is on its trial.

I confess I look at the Association with the eyes of an insurance practitioner, and therefore as a partisan. The report says that the Association exists to safeguard the whole profession, but wisely makes it clear that the whole profession may be soon involved in insurance work; "In the immediate future it is practically certain that extension of medical benefit, in some form or another, to include either other sections of the community, or other kinds of medical service, or both, will bring within the ambit of national insurance many practitioners who are not at present directly affected." The panel practitioners' interests, therefore, are the interests of the whole profession.

What has a conference of Local Medical and Panel Committees to do with a Ministry of Health? Is its pious hope, "that a Ministry of Health should be created to take over from the existing Government departments such duties as are concerned with the health of the community and to deal with those duties only," likely to cause the Government to deviate one hair's breadth from its course? Sir Edwin Cornwall thought so highly of the advice of medical men that his advisory committee consisted almost wholly of representatives of approved societies. Thanks to the Association this was afterwards changed.

Every insurance practitioner knows that the care and treatment of discharged disabled soldiers and sailors will be a heavy tax on his time and energies. He also knows that his remuneration is totally inadequate. The Association agrees with these views and asks for better terms. But while failing to obtain any assurance that this request would be favourably considered by the Treasury, neverthe-

less pleads that the new arrangements shall not exclude practitioners who hitherto have abstained from insurance practice from undertaking the treatment of discharged disabled soldiers and sailors.

Whilst the Association has submitted to the Commissioners questions of life and death to the profession and has received replies saying "that the contents of its letter have been noted," or "that no assurance could be given that its request would be favourably considered," the Association asks nevertheless for the care of the wives and children of these discharged disabled soldiers and sailors. There is, surely, inconsistency in this.

On the subject of "production of medical cards, onus of proof," the course for the Association to take is so clear that if it allows itself to be browbeaten its dissolution should be welcomed by all. We sink to the level of imbecility when we begin to discuss whether a man who seeks treatment should prove whether he is entitled to it or not. An insurance patient who cannot refuse insurance treatment if he likes becomes at once a pauper and a slave. The panel doctor needs only to be branded on the forehead to make his degradation complete.

I write in the hope that the result of the conference will be to convince the profession that we have in the Association a doughty champion, who can make the Commissioners realize that they have a foeman worthy of their steel.—I am, etc.,

Exeter, Sept. 23rd.

J. A. W. PEREIRA.

TREATMENT OF VINCENT'S ANGINA.

SIR,—On page 404 of the JOURNAL of September 22nd a letter is published from Dr. F. E. Taylor and Captain W. H. McKinstry regarding the treatment of Vincent's angina. I should like to call attention to the fact that the first publication on this subject since the beginning of the war appeared in the *Proceedings of the Royal Society of Medicine*, vol. ix (Medical Section), pp. 51-60; also in the *BRITISH MEDICAL JOURNAL*, March 1st, 1916, and a little later in the *Journal of the Royal Army Medical Corps*. Salvarsan was mentioned as being an excellent treatment for the condition, but unsatisfactory for general use among the troops.

Among Canadian troops the mixture recommended by me in the above paper is still being used with very satisfactory results. Of late, on several cases, however, I have been using, in place of the arsenic in the prescription, a saturated solution of antimony and potassium tartrate, which is much less poisonous, and which would seem to be equally good.

It might be mentioned that all reference to my work was omitted in Taylor and McKinstry's article, which was due probably to the "exigencies of space."—I am, etc.,

Folkestone, Sept. 23rd.

F. B. BOWMAN, Major C.A.M.C.

THE SUPPLY OF MORPHINE, ETC., TO ARMY MEDICAL OFFICERS.

SIR,—An editorial appears in the current issue of the *Pharmaceutical Journal* on the subject of the right to supply medical men serving in the army with cocaine, morphine, etc., on their personal written order for the same, and the view expressed in an editorial in the same journal on July 28th is emphatically confirmed that it would be a direct contravention of the regulations to do so.

If this view is correct, it appears to me that medical men serving in the army are placed in a difficult, not to say somewhat ignominious, position. But is it correct? If words have any meaning, I should say not. The regulations state that such drugs shall not be sold except to "authorized persons," and further on the regulations define authorized persons as including "duly qualified medical practitioners." Surely a man does not cease to be a duly qualified medical practitioner because he takes up His Majesty's commission in the army, whether as a medical officer or a combatant. In the north of England, as elsewhere, there are many medical practitioners with commissions in the army who are at the same time able to do a certain amount of private work. The reading of the regulations suggested as correct would make it an offence against the Defence of the Realm Regulations to supply such an officer with a tube of morphine tablets or a small quantity of cocaine. This surely would be an intolerably

unfair restriction on the legitimate freedom of action of medical practitioners so placed, and I cannot think that such can be the intention of the authorities.—I am, etc.,
WILLIAM MARTIN.
Newcastle-upon-Tyne, Sept. 24th.

Obituary.

THE death of Lieut.-Colonel FREDERICK ROBERT SWAINE, I.M.S., of Ranchi, removes, perhaps, the oldest European official resident in the Province of Bihar and Orissa. Colonel Swaine came to Ranchi in the Seventies, and, after spending the greater part of his service in that station, settled there when he retired twelve years ago. He had a wonderful knowledge of the town and its inhabitants, and had done valuable service as a municipal commissioner for a great many years.

WE regret to record the death of Dr. ARTHUR BADCOCK, who died suddenly on September 16th, after an illness of some months' duration. Dr. Badcock was the son of the late Rev. J. Badcock, D.C.L., Vicar of Stroud, Gloucestershire. After completing his studies at the Leeds School of Medicine he qualified in 1886, was appointed resident medical officer to the York Dispensary, and subsequently settled down in practice in succession to Dr. Hall at Clarence House. In 1902 he succeeded his partner, Dr. Weekes, as honorary medical officer to the York Dispensary, of which for some years he was senior honorary officer. He took a keen interest in the management of the York Dispensary and in all professional matters in York. From July, 1914-1917, he was president of the York Medical Society. He was held in high esteem by his medical colleagues and by a wide circle of friends and patients. He leaves a widow, the daughter of the Rev. J. L. Challis, late Rector of Hartwell-with-Stone.

The Services.

EXCHANGE.

CAPTAIN R.A.M.C., in F.A. three years in France, would like to exchange with M.O. in England.—Address, No. 3300, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.2.

Medical News.

THE American Red Cross has appropriated £20,000 for medical research work in France.

THE opening meeting of the thirty-sixth session of the West London Medico-Chirurgical Society will be held at the West London Hospital on Friday, October 5th, at 8.30 p.m.

THE seventh Norman Kerr Lecture will be delivered before the Society for the Study of Inebriety by Major W. McAdam Eccles, R.A.M.C.(T.F.), on Tuesday, October 9th, at 5.30 p.m., in the Robert Barnes Hall, 1, Wimpole Street, Cavendish Square, London, W.1. The subject of the lecture will be War and Alcohol.

LIEUT.-COLONEL SIR ALFRED PEARCE GOULD will deliver the first Hunterian Lecture before the Hunterian Society on Wednesday, October 3rd, at 9 p.m., at the House of the Royal Society of Medicine, 1, Wimpole Street, W. The subject of the lecture will be Modern Antiseptics.

MESSRS. LONGMANS announce for early publication a volume by Mr. Henry Carter, member of the Liquor Control Board, entitled, *The Control of the Drink Trade: A Contribution to National Efficiency, 1915-1917*, giving a full account of the work of the Board in restricting the sale of drink, and providing industrial canteens, and also of the State purchase of enterprises at Gretna, Carlisle, and elsewhere.

THE Special Health Committee of the Calcutta Corporation recently considered whether the present campaign against rats and the system of payment of a reward of half an anna for each live rat should be continued. The campaign was started several years ago by the Plague Department, and has been continued with indifferent results. During the last year 138,386 rats were killed and 40,213 dead rats were found in the streets. The total cost of the campaign works out to Rs. 3,374 per annum. In

Bombay during last year the total expenditure was Rs. 35,590, and the number of rats collected was 943,346. In Madras the total expenditure during the last year was Rs. 6,709, and the total number of rats killed was 138,611.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

THE telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are: (1) EDITOR of the BRITISH MEDICAL JOURNAL, *Attingham, Westrand, London*; telephone, 2631, Gerrard. (2) FINANCIAL SECRETARY and BUSINESS MANAGER (Advertise-ments, etc.), *Attingham, Westrand, London*; telephone, 2630, Gerrard. (3) MEDICAL SECRETARY, *Meilsora, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

J. D. asks for information or references in medical literature relating to the symptoms, and more particularly the post-mortem appearances, in any known cases of poisoning by "bitumastic"—an anticorrosive fluid and paint applied to the water tanks of ships, etc.

LETTERS, NOTES, ETC.

TREATMENT OF WHOOPING-COUGH.

DR. T. DUNCAN NEWBEGGING (Abington, Lanarkshire) writes that he has had satisfactory results during a recent epidemic of whooping-cough by the following treatment. A small wet brush is dipped into crystals of zinc sulphate so that they adhere; the brush is applied to the fauces, chiefly to the uvula, the patient being instructed to keep the powder in place as long as possible. In some instances one application has effected a cure, even in fully established cases; in others two were necessary.

ACTION OF ADRENALIN.

DR. I. HARRIS (Liverpool) writes: In an interesting paper on trench nephritis Lieut.-Colonel Michell Clarke, M.D., F.R.C.P., in the JOURNAL of August 25th, recommends adrenalin in the treatment of those cases "attended with low blood pressure." May I point out that adrenalin does not exercise any permanent influence on the blood pressure? Adrenalin administered intravenously raises the pressure for a few seconds only; adrenalin given by the mouth has a more lasting effect on pressure, but only because the process of absorption of this substance into the circulation is extended. Adrenalin is not only indicated in low blood pressure, but is equally valuable in cases of nephritis attended with high blood pressure. Adrenalin acts as a diuretic and diminishes albuminuria in cases of nephritis irrespective of blood pressure. A case with a high blood pressure, published in the last issue of the *Liverpool Medical Journal*, has done extremely well under adrenalin.

INFECTIVE JAUNDICE—A CORRECTION.

LIEUT.-COLONEL W. E. HUME asks that the following corrections may be made in the paper on infective jaundice by Dawson, Hume, and Bedson, published in the JOURNAL of September 15th, 1917: (1) Page 345, second column, line 36, "September 15th, 1917," read "April and May, 1916." (2) As the paper only treats of one type of infective jaundice, the title would be better described "Infective Jaundice (Spirchaetosis Icterohaemorrhagica)."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive postage *retroactive* letters addressed either in initials or numbers.

NOTES FROM THE ANGLO-RUSSIAN HOSPITALS.

BY

SIR HERBERT F. WATERHOUSE, F.R.C.S.,
SURGEON-IN-CHIEF,

W. DOUGLAS HARMER, M.C.CANTAB., F.R.C.S.,
SURGEON,
AND

CHARLES J. MARSHALL, M.S.LOND., F.R.C.S.,
ASSISTANT SURGEON.

We returned some months ago from Russia after respectively eleven, eleven and a half, and six and a half months of service with the Anglo-Russian hospitals. In the hope that a record, brief and imperfect as it must be, of our work among the Russian soldiers may be of interest to our surgical colleagues in this country and on the Western front, we venture to direct attention to certain of the results of our experience, trusting that here and there a hint of importance may be gleaned by them.

We would at the outset draw attention to the fact that, owing to the stupidity of a Russian customs official on the Russo-Finnish frontier, who, in spite of our strenuous protest, couched in very indifferent Russian, tore up the manuscript of our notes of several cases, under the notion that they contained treasonable matter, this communication necessarily lacks many details of statistical importance, and that its value is impaired by the loss of these notes, because we have had to rely, in their absence, partly upon memory instead of on manuscript. Fortunately one of us (C. J. M.) was lucky in meeting with no such obstacle in his journey to England, and his notes have enabled us to fill up many blanks and to check our memory regarding many details.

The Anglo-Russian Hospital, which owes its inception largely to the energy and devotion of Lady Muriel Paget, was divided into four sections: (1) The hospital in Petrograd, in the Dmitri Palace on the Nevsky Prospect, the main street of Petrograd, an excellently equipped institution of 200 beds with a complete staff and an admirably arranged x-ray department and bacteriological laboratory, all the necessary plant having been brought from London. (2) The field hospital, a mobile unit in tents, with 42 ambulance and transport carts, 125 Russian sanitars (orderlies), and 8 British nurses, was attached to the Russian Guards and moved with them. The Russian Guards should be considered rather as an army than as a regiment, as we were informed that they numbered 120,000 men. (3) A hospital in a large barracks at Lutsch, under the care of Mr. Geoffrey Jefferson, M.S.Lond., F.R.C.S. Eng. In this hospital a vast amount of surgical work was most efficiently performed, but we had no direct connexion with it except that two of us visited it occasionally as consulting surgeons. (4) A fleet of 22 motor ambulances, which proved of the greatest value. The main roads in Russia are, in general, excellent, though in summer terribly dusty. The side roads are very bad. It was our practice to keep the motor ambulances on the main roads and to trust to horse transport to bring the wounded from the dressing stations to the main roads, where they were transferred to our admirable motor ambulances. During the eleven months November, 1915, to October, 1916, more than 6,000 patients received treatment in the Anglo-Russian hospitals. The time that the patients remained under treatment was widely different in the various hospitals. At the front it rarely exceeded one week; in Petrograd, owing to the lack of convalescent homes in Russia, the patients had to remain in hospital until their wounds were completely healed.

I. The Treatment of Infected Gunshot Wounds, with Special Reference to Compound Fractures.

As so many gunshot wounds are associated with a compound fracture of a bone it is advisable to consider their treatment together. Surgical opinion is divided on the question whether antiseptics should be employed or not. We confess that we can give no definite answer. We are convinced that strong antiseptics, such as pure carbolic acid, while they are distinctly harmful to the tissues, do not sterilize the wound; their employment we unhesitatingly condemn. It is more difficult to dogmatize as

regards the comparative value of eusol, prepared according to the formula of Professor Lorrain Smith, and the hypertonic saline solution of Sir Almroth Wright. We have treated hundreds of infected wounds and of infected compound fractures both with eusol and with hypertonic saline solution; we are not yet convinced which method presents the greater advantages. We can only state that both are, in our opinion, a great advance on older methods of treatment.

II. Tetanus.

From this scourge we were favoured with an extraordinary immunity, notwithstanding the fact that for many months we could very rarely obtain antitetanic serum. So far as we were able to ascertain only three of our patients suffered from tetanus. One patient, under the care of W. D. H., developed the disease on the fifth day after admission and died two days later. In the two other cases the incubation period was long (nineteen and twenty-two days respectively). In the absence of antitetanic serum we had to fall back upon the carbolic acid treatment. We employed far larger doses of carbolic acid than are generally recommended; thus for the first three days we administered hypodermically 1 oz. of a 5 per cent. solution of carbolic acid every four hours. In neither case was carboloria produced and both made excellent recoveries. Our experience is in striking contrast to that gained by us in the R.A.M.C.T. hospitals, where we, in the earlier days of the war, treated patients from the Western front who had not, as is now invariably the case, received a prophylactic injection of antitetanic serum. We can only attribute the difference in the incidence of tetanus to the contrast between the dusty, comparatively uncultivated soil of Volhynia and the highly-manured fields of Flanders.

Immediately on admission every gunshot wound was freely opened under anaesthesia, and finely powdered potassium permanganate (about 1 oz.) was rubbed into all the wound surface. This caused a considerable development of heat, the wound "smoked" and assumed a blackened appearance. The superficial necrosis of the tissues cleared away in four to five days, at the end of which time the wound had a healthy granulating aspect and union by second intention rapidly followed. This treatment, which we carried out in hundreds of cases of infected wounds (including compound fractures), was attended with the happiest results. It did not appear to retard the healing of the wounds, and, so far as we are aware, in no case did tetanus subsequently result. We consider the rubbing into the wound of powdered potassium permanganate an admirable method of treatment of gunshot wounds, especially in cases in which antitetanic serum is not available, and we recommend it with confidence.

III. Bullet Wounds of the Brain and Hernia Cerebri.

Of these injuries we had a large experience. Thus, in one convoy of wounded, we admitted fourteen patients suffering from rifle or shrapnel wounds of the brain. We learnt to employ the freest possible drainage, for it soon became apparent to us that the chief mortality was due to septic infection, and that the only way to avoid it was to establish the most complete drainage of the wound secretions. We therefore opened the wound widely, removed all loose fragments of bone, and, after securing efficient drainage, covered the open wound with gauze moistened with formalin lotion (2 per cent.). It is noteworthy that of these fourteen cases in this one convoy twelve left the field hospital apparently well on the road to recovery at the end of seven days from admission, and that only two died in hospital. Attention should be drawn to the difference in prognosis between cases in which the bullet perforates the skull and those in which it remains embedded in the brain. In our experience the vast majority of the former recover, of the latter die. In the base hospital in Petrograd we had a large number of cases of hernia cerebri, the result of gunshot wound of the brain. The routine treatment was to cover the hernia cerebri with gauze soaked in formalin solution (2 per cent.) for three days. At the end of this period the hernial protrusion was covered by a brownish membranous slough, and bacteriological examination proved that it was practically sterile. The protrusion was then shaved off level with the opening in the skull and the formalin dressing reapplied. As soon

as the wound was healed an operation for closure of the gap in the skull was undertaken. This was effected by turning into the opening fragments chiselled from the outer table of the skull (pericranial surface inwards) while still maintaining their connexion with the pericranium at the margin of the aperture. In other cases thin layers of costal cartilage were employed for this purpose. In every case Cargill membrane or egg membrane was inserted between the brain substance and the bone or cartilage. With the exception of one case, in which an abscess of the brain was situated underneath the hernia cerebri (this abscess was diagnosed and drained, but subsequently burst into the lateral ventricle with fatal result), this procedure secured excellent results in every instance.

IV. Compound (Gunshot) Fractures of the Lower Ends of the Tibia and Fibula.

We were amazed to find how frequent such injuries were. On one occasion we found no fewer than eleven patients suffering from gunshot compound fractures situated a few inches above the ankle-joint in successive beds in the Petrograd hospital. We are unable to account for the frequency of such injuries. We were informed by the Russian military authorities that the reason of their common occurrence was that the German and Austrian soldiers were ordered to fire at the feet of the troops opposed to them. As we have, in our experience in the 1st and 4th London General Hospitals, met with no such preponderance of similar injuries, we are not convinced that the above explanation suffices to explain the enormous number of cases we had to deal with in Russia. We refer to the matter chiefly to draw attention to the advantage to be obtained in the treatment of such injuries, especially in cases in which the deformity is marked, by subcutaneous tenotomy of the tendo Achillis, a procedure we carried out in a large number of instances with most satisfactory results.

V. Suppurative Arthritis.

It is essential to distinguish between suppurative arthritis due to a wound of the joint and those cases that are due to metastatic infection from a pyogenic focus, whether due to a wound or not. In the treatment of metastatic pyogenic arthritis we invariably adopted the plan laid down by the late John B. Murphy of Chicago, to which attention was directed by one of us (H. F. W.) in a contribution to the *BRITISH MEDICAL JOURNAL*, February 6th, 1915, entitled "The employment of ether in surgical therapeutics." In every case of metastatic pyogenic arthritis that came under our care we refrained from incision into the joint and drainage, as we knew from past painful experience that such treatment almost invariably resulted in bony ankylosis. Convinced converts to the Murphy theory, we aspirated the pus from the joint cavity, injected ether or a 2 per cent. solution of formalin in glycerin and applied adequate extension; by this we mean 20 lb. for the knee-joint; twenty-four hours later we reaspirated the joint and reinjected ether or formalin glycerin (2 oz. for the knee-joint), and continued this treatment daily until the joint recovered. So far as we are aware, in no case did ankylosis result. The results obtained in suppurative arthritis due to a wound of the joint were far less favourable. In such cases ether was inadmissible, as its vapour forced its way through the opening into the joint. Formalin glycerin was no more satisfactory, and we were driven therefore to employ free drainage combined with continuous eusol irrigation. In many such cases osseous ankylosis resulted, and in two instances amputation had to be resorted to.

VI. Bone Grafting.

This measure was employed to secure osseous union in several cases in which the loss of bone caused by a gunshot wound was too great to permit of union of the fragments. In no case was it attempted until the wound in the soft parts had completely healed. Then the fractured ends of the bone were sawn off and an intramedullary splint, obtained from the opposite tibia (the tibia was the bone affected in the majority of instances), was inserted into both revivified ends of the fractured bone and fixed securely with screws or nails. All these cases yielded a satisfactory result.

VII. Intestinal Worms.

The Russian soldier is a very frequent host of the *Ascaris lumbricoides*. In the large majority of patients proved to be infested by this worm no symptoms of ill health could be traced to its presence. The number of soldiers who vomited these worms after operation was truly amazing. One day, out of four patients who had been operated upon three vomited one or more ascarides. During our service at the field hospital a Siberian soldier was admitted nearly moribund from general peritonitis. On opening the abdomen much pus and gas escaped. In the peritoneal cavity were five ascarides, which had found their way out of the small intestine through three circular perforations of the ileum, all situated in a segment of bowel $1\frac{1}{2}$ in. in length. We were unable to discover the cause of these intestinal perforations. The patient died a few hours after resection of the affected segment of the ileum.

VIII. Gas Gangrene.

This terrible condition was the cause of the majority of the deaths at the field hospital. Many of our patients had lain, after being wounded, in No Man's Land for four or even five days, and on admission were suffering from virulent gas gangrene, with its vilely putrescent odour and grave toxicæmic symptoms. Immediate amputation, wherever feasible, was performed, and, owing to the splendid vitality of the Russian, and more especially the Siberian soldier, in a large majority of cases proved to be life-saving. In cases in which amputation was not possible—for example, in infected wounds of buttock and back—the freest incisions, combined with rubbing into the opened-up wound surfaces of powdered potassium permanganate, secured, in a considerable number of instances, an unexpectedly favourable result. Two things we learnt definitely about the treatment of gas gangrene: (a) That injection of hydrogen peroxide into the infected tissues, warmly recommended in some quarters in the expectation that the nascent oxygen will have an inhibitory effect on the development of the infecting anaerobic microbes, is entirely harmful, as it increases the tension in the affected part, whereas the desideratum is the relief of tension; and (b) that when gas gangrene affects a muscle the entire muscle should be extirpated from its insertion to its origin. This procedure we carried out in a large number of instances with very satisfactory results. A case successfully treated by W. D. H. may here be mentioned.

A Russian colonel, who had been left for five days in the open after being wounded, was admitted with extensive gas gangrene involving the whole of the upper extremity, and spreading for several inches on to the chest wall. Although there seemed to be small hope of saving life, as the patient's condition appeared desperate in the extreme, disarticulation at the shoulder-joint was performed and an intravenous injection of normal saline solution given on the operating table. Despite the extension of the gas gangrene to the subcutaneous tissue of the chest, the patient made a rapid recovery.

Isolated instances of the development of gas gangrene twenty, thirty, or even forty days subsequent to the infliction of the wound, came under our care at various times. The following case shows that the infecting microbe may remain dormant for sixty-seven days and then produce gas gangrene:

A Siberian soldier was admitted into the Petrograd hospital suffering from a comminuted fracture of the upper end of the right femur. The limb was three inches shorter than the left leg. His papers proved that he had been wounded by a fragment of a bomb sixty-six days prior to admission. X-ray examination revealed the presence of a fragment of metal the size of a filbert, wedged in between the overlapping fragments of the femur. The day after admission the edges of the wound became black and the discharge was characteristically putrid. Gas crepitation was made out around the wound, and Dr. Rosher, bacteriologist to the hospital, demonstrated *B. perfringens* in the discharge from the sinus. The patient's condition was grave in the extreme; the pulse was 140 and the temperature 103.6°. The sinus was opened widely, the bomb fragment extracted, and all the gangrenous tissue removed with scissors. The entire wound was rubbed with powdered potassium permanganate and constant irrigation with a strong solution of the same chemical was instituted. The disease was thus promptly checked and in five days the pulse and temperature fell to normal. It is of great interest to record that, a few days later, the patient developed bilateral suppurative mastoiditis and that from the gas-containing pus of the abscess on the left side *B. perfringens* was isolated.

IX. Gas Gangrene Pyaemia.

We know of no case in which gas gangrene pyaemia has been recorded, but as we were many months in Russia and unable to obtain the medical journals, we may readily have missed a notice of this condition. That there is such a thing as gas gangrene pyaemia is, we think, proved by three cases.

1. The patient just mentioned in whom the *B. perfringens* was discovered in the pus evacuated from an acute mastoiditis.
2. A young Siberian soldier was wounded near Riga, January 30th, 1916, and admitted into the Petrograd hospital on February 3rd, suffering from a fracture of the body of the left scapula caused by a bomb. There was no wound of exit. On February 4th his condition was grave, the pulse was 135, and the temperature 103.5°; there was a brawny swelling just behind the left clavicle. An incision into this swelling evacuated much stinking gaseous pus in which the *B. aerogenes capsulatus* was discovered by Dr. Rosher. The following day two small abscesses were incised, of which one, over the left tibia, contained a tiny fragment of metal and the pus evacuated contained the *B. aerogenes capsulatus*; the other, situated on the right thigh, contained the same organism. This patient, under treatment by eusol intravenously, made an excellent recovery. Naturally, as the former of the two small abscesses was the result of a wound, we lay no claim to its being of pyaemic origin. The second of the two abscesses, which was unassociated with any wound and contained the *B. aerogenes capsulatus*, appears to us to sustain our contention that it was pyaemic in origin. It must be admitted that blood cultures made by Dr. Rosher proved negative, but this is not surprising as, prior to the abstraction of the blood for the purpose of obtaining a culture, intravenous infusion of eusol solution had been employed.
3. Late one night a soldier was admitted into the field hospital suffering from gunshot wounds of the head, of the left humerus, and of the soft parts of the right thigh. The wounds were clean perforations, and the patient's condition appeared to us 'in no way serious. At 2 p.m. the next day he was almost pulseless. Examination revealed a large area of gas gangrene situated over the right lower chest and upper abdomen. Incision into this crepitant area gave exit to a large quantity of gas-containing fluid, and the subcutaneous and muscular tissues showed the typical appearance of gas gangrene. As we were at the field hospital and, at the time, overwhelmed with work, no bacteriological examination was made, but the two of us (H. F. W. and C. J. M.) who saw the case are convinced that it was one of pyaemic gas gangrene. The area of the gangrenous patch was at least twelve inches from the nearer of the two wounds. It is difficult to avoid the conclusion that the microbes were conveyed to the part by the blood stream.

X. Intravenous Infusion of Eusol Solution.

This method of therapeutics was employed by us in a large number of cases, and we entertain the highest opinion of its value as a life-saving method in many apparently hopeless cases of septicaemia and pyaemia. A striking example of its efficiency was afforded by Case 2 recorded above. Several of our colleagues who saw this patient were convinced that the young man must die, yet, thanks to intravenous eusol infusion, he made an excellent recovery. In many instances in which, for some reason not discoverable, the patient appeared to be steadily going from bad to worse from some form of septic infection, a single intravenous infusion of eusol turned the scale in favour of recovery, and this improvement was, as a rule, rapid. We may mention that in these intravenous injections we used a large dose of eusol. Almost invariably, in cases that appeared to call for its employment, 100 c.cm. of Lorrain Smith's solution of eusol were given intravenously, and we had no hesitation in repeating this dose daily for several days. No toxic symptoms were ever noticed. So far as our memory serves, our results in cases of streptococcal septicaemia were, in general, disappointing. In three such cases the intravenous injection apparently had no good effect, and a similar failure has recently been observed by one of us (H. F. W.) at the 4th London General Hospital. We can offer no explanation of the comparative inefficiency of the treatment in infections due to streptococci in contradistinction to its sterling value in other bacterial septicaemias.

XI. Tendon Transplantation in Cases in which too long a Segment of a Motor Nerve has been Destroyed to allow of its Ends being Sutured.

Two such cases came under our care, and were operated upon with very satisfactory results.

- (a) A large splinter of shell had carried away the upper four inches of the fibula, together with the external popliteal nerve and a considerable mass of muscular tissue. There was complete paralysis of motion and sensation in the distribution of the external popliteal nerve. The limb below the knee was useless, the ankle-joint fully extended, and the toes flexed. The

following operation was carried out by H. F. W.: A vertical incision, five inches in length, was made over the tendo Achillis, which was divided by two longitudinal incisions into three equal segments—an inner, middle, and outer. The three strips of tendon were divided transversely just above their attachment to the os calcis. An incision just above the external malleolus exposed the tendons of the peroneus longus and brevis. By tunnelling through the subcutaneous tissue the outer segment of the divided tendo Achillis was brought into contact with the two peronei tendons, and a small perforation having been made into each of these tendons the cut end of the outer segment of the tendo Achillis was brought through each perforation and fixed securely by means of chromicized catgut sutures. In a similar manner the inner segment of the tendo Achillis was brought through perforations in the tendons of the tibialis anticus, the extensor longus digitorum, and the extensor proprius hallucis, just above the internal malleolus, and fixed by means of sutures. The middle segment of the tendo Achillis was left unattached in the hope, which was justified, that it would unite with the short distal fragment of the tendon. The foot could now be brought to a right angle with the leg. The after progress of the case was excellent, the patient being able to walk satisfactorily and to extend his toes.

As the method gave so excellent a result, it was repeated in the case of a girl, aged 8 years, admitted into the Victoria Hospital for Children early in February, 1917, suffering from paralysis of all the muscles supplied by the external popliteal nerve, the result of infantile paralysis. In this case we were also much gratified by the result obtained, and we venture to recommend the method in similar cases.

Since the above was written we have obtained a third equally satisfactory result.

One of us (H. F. W.) has since returning from Russia had under his care two patients suffering from paralysis of the quadriceps extensor crureus muscle, the result of acute anterior poliomyelitis. In one case the tendons of the biceps flexor cruris and of the gracilis were inserted into the suprapatellar tendon of the quadriceps with excellent result, the patient being now able to extend the knee satisfactorily. The second case has been operated upon too recently to permit of any report as to the results.

(b) As the result of a gunshot wound of the right humerus a considerable comminution of the middle third of the humerus had occurred, with much callus formation and paralysis of the musculospiral nerve. An extensive dissection failed to reveal the distal end of the musculospiral nerve. It was then decided by H. F. W. to divide the tendon of the flexor carpi radialis, under the anterior annular ligament, and to insert it into the extensor tendons of the thumb and fingers three inches above the level of the wrist. This operation was easily performed, and the patient was well satisfied with the result, as he could extend the thumb and fingers completely, though, naturally, all the digits had to be extended at the same time.

XII. Surgery of Arteries.

Simultaneous Ligation of Common Femoral, Superficial Femoral and Deep Femoral Arteries.—This remarkable case, abstracted from notes by C. J. M., appears worthy of record from the fact that no gangrene followed the simultaneous ligation of all the above arteries.

The patient was admitted into the field hospital three days after he had been wounded by a fragment of shell which entered just below the left anterior superior spine of the ilium. There was no wound of exit. Scarpa's triangle was occupied by a brawny mass, the skin was discoloured, and distinct pulsation was readily made out. As the skin was threatening to rupture, an incision was made over the line of the main artery. The cavity of the false aneurysm was opened, and some 10 oz. of recent clot were turned out of the wound; furious haemorrhage occurred from the depth of the wound. Owing to the staining and infiltration of the tissues it was difficult to recognize the landmarks. The superficial femoral artery was ligated (by H. F. W.) 2 in. below Poupart's ligament. This had no effect in diminishing the bleeding. The common femoral artery was then ligated. This almost completely arrested the haemorrhage and allowed inspection of the wound. It was then clearly demonstrated that the shell fragment had torn the profunda artery completely across, exactly at the site of its origin from the parent trunk, and had thus left a hole in the latter which involved the lowest part of the common femoral and the uppermost portion of the superficial femoral arteries; the divided end of the deep femoral artery was then ligated.

The operator (H. F. W.) desires to express his thanks to his colleague, Professor Graham Aspland, for his valued help under very trying circumstances.

We, naturally, felt certain that gangrene must supervene, and the only question in our minds was as to its extent. Fortunately the circulation was completely restored, and when the patient left the hospital, ten days after the operation, the circulation, even in the toes, appeared normal. C. J. M. in his note on this case lays stress on the fact that the gradually increasing pressure on the vessels may for some time have allowed a certain amount of blood to run through the superficial femoral artery, and thus have given time for the anastomosing circulation to have been fully restored in sufficient degree to maintain the vitality of the limb.

Syme's Amputation Performed after Ligature of Posterior Tibial and Plantar Arteries.—A volunteer had been excused military duty owing to osteomyelitis of the tarsus eight years previously, with resulting ankylosis of the ankle-joint. He had, however, insisted on serving as a volunteer.

His patriotism was ill rewarded, as marching caused a recurrence of his tarsal osteomyelitis with abscess formation in the foot and numerous secondary abscesses. One of these, situated midway between the internal malleolus and the heel, had been incised in such a way that the posterior tibial artery had been severed at its point of bifurcation into the two plantar arteries. Secondary haemorrhage occurred in the train and on admission to the Petrograd hospital bleeding was still going on. The three vessels were ligated. The next day much carious bone was removed from the tarsus, but, in spite of free drainage, it was found necessary to amputate the foot. After consultation it was decided to attempt a Syme's amputation in spite of the fact that the above vessels had been ligated. The amputation was skillfully performed by our colleague, Captain Gardner, and as some sloughing was anticipated larger flaps than usual were made. Union by second intention was secured and an excellent, though somewhat bulky, stump was obtained.

An interesting case under the care of W. D. H. deserves mention:

Fracture of Base of Skull, Rupture of Both Branches of the Middle Meningeal Artery, and Laceration of Intracranial Venous Sinuses from Shell Concussion without External Wound: Recovery.

The patient could only remember that a large shell burst near him and that after this he lost consciousness. He had no wound and no bruising was discovered. Typical symptoms of intracranial haemorrhage supervened. On trephining, a long fracture was discovered running from the parietal region towards the base of the skull. Both the anterior and posterior branches of the middle meningeal artery were ruptured and had to be ligated. Much bleeding from the basal intracranial sinuses (petrosal?) necessitated firm plugging for its control. The patient made a rapid recovery.

XIII. Aeroplane Bombs and Bomb Wounds.

One of us (H. F. W.), prior to visiting Russia, had a terrible experience of the wounds caused by bombs dropped from Zeppelins, as he had been surgeon for the day at Charing Cross Hospital when the Zeppelin raid took place in September, 1915. On this occasion 100 patients were admitted into Charing Cross Hospital, of whom fourteen were dead on admission, and nine others died within twelve hours. In every wound examined bacteriologically the *Bacillus aerogenes capsulatus* was identified. The same organism was found in every case of wound caused by a bomb dropped from an aeroplane admitted into the Petrograd hospital. At the field hospital we had no opportunity of making bacteriological examinations, but, warned by previous experience, we freely opened every such wound and rubbed into the tissues the powdered potassium permanganate as mentioned above. The fact that in every Zeppelin and aeroplane bomb wound examined at Charing Cross Hospital and the Petrograd hospital the *B. aerogenes capsulatus* was demonstrated, makes us suspect that the outer casing of the bomb must have been infected with a culture of this micro-organism. If such be the case, science has surely never before been made to serve so fiendish a purpose.

On the Russian front we were greatly pestered with visits from German aeroplanes that dropped bombs with annoying frequency and regularity. Generally our unwelcome visitors appeared at about 7 a.m. and 6 p.m. Two of us were knocked down by the concussion of the air, but fortunately the bomb fragments missed us. The wounds caused by the bombs were truly terrible. Wounds of the limbs generally called for immediate amputation. Wounds of the abdomen were almost invariably fatal. Thus, on one day in which 140 bombs were dropped in our village, seven of which fell in our hospital grounds, six patients were admitted suffering from laceration of the intestines, and death resulted in every instance. In our own hospital there was fortunately no fatality from aeroplane bombs, and we attribute this immunity largely to the fact that we had surrounded our tent wards with walls of sandbags 4 ft. high. Although every tent was perforated by bomb fragments repeatedly, none of our patients received any injury.

XIV. Bipp.

Professor Rutherford Morison was good enough to send to one of us (H. F. W.) a reprint of his contribution on the

treatment of infected suppurating war wounds.¹ Unfortunately by the time we received this reprint we had already left the Russian front, and had therefore no opportunity of making trial of bipp in recent wounds. We, however, employed it in several cases at the Petrograd hospital, and have since used it largely at the 1st and 4th London General Hospitals R.A.M.C.(F.) and at Charing Cross Hospital. Bipp, which is composed of bismuth subnitrate 1 part (by weight), iodoform 2 parts, and soft paraffin in sufficient quantity to make a stiff paste, has proved entirely satisfactory in our hands and has yielded results equalling those described by Professor Rutherford Morison. We have formed the opinion that, in extensive gunshot compound fractures, free opening of the wound, cleansing it with ether or alcohol, and then packing the cavity firmly with bipp, will, in the great majority of cases, ensure the safe and painless healing of the fracture, and that this method of treatment is a distinct advance in surgical therapeutics. Our best results have been obtained with bipp in wounds that were non-perforating, as in such the paste can be more thoroughly packed away into the recesses of the wound than with a perforating wound. We have been greatly impressed with the fact that splinters of bone of considerable size, completely detached from their surroundings, can be removed from the wound, washed with ether, replaced in the gap in the bone, and there help to consolidate the fracture in the presence of bipp. We can also confirm the statements of Professor Morison (1) that when bipp is employed "all infected discharge comes from the surface of the wound in the neighbourhood of the skin. The paste in the depths is clean and should not be disturbed." (2) That a weekly dressing is all that is required; and (3) that no symptoms of iodoform poisoning need be feared.

The sole objection we have noticed in cases treated by bipp has been the occurrence of a dermatitis in the skin surrounding the wound. This, which we believe to be due to the action of nascent iodine, has been noticed in six cases. Captain J. A. Willett, R.A.M.C.(F.), has demonstrated to us that, in the presence of this dermatitis, the correct treatment is to remove the iodoform and employ only the bismuth subnitrate in the paste. Recently we have been making use of bipp in which the bismuth subnitrate and iodoform are employed in equal parts, and we have found that, while the efficiency of the paste is in no way impaired, the tendency to cause dermatitis is distinctly lessened.

XV. Powers of Resistance of the Russian Soldier.

The Russian soldier is an ideal patient. His powers of resistance are indeed marvellous. Practically every patient who came under our care was a countryman, accustomed to live in the open air, inured to extremes of heat and cold, and able to undergo major operations with a minimum of shock. One instance will illustrate the above.

At 6 o'clock one evening, one of us (H. F. W.) amputated in the middle of the thigh for gas gangrene of the leg and knee regions in the case of a Siberian soldier. The next morning, at 7 o'clock, we were awakened by the sound of the anti-aircraft guns and took refuge in one of the dug-outs. This was a necessary precaution, as every tent in the hospital was perforated by bomb fragments. Seated in the dug-out we found our patient of the previous evening quietly smoking a cigarette! In response to our inquiry how he had got there, he informed us that he had placed his arm round the neck of a fellow-patient and had hopped to the dug-out on his sound leg!

It is well known that wounds received in very cold climates tend to heal slowly, and this was noticeable during the winter months in some of our patients. The protracted healing of the wounds appeared to be due to a sluggish circulation in the part affected, but we think that a contributing factor was to be found in the poor condition of many of the patients, who were often ill-nourished and anaemic. The Russian peasant seems to be able to sustain life on a minimum of food. Weak tea, black bread, soup, and "kasha," a kind of porridge made chiefly of millet seed, with meat twice a week, make up for him what he considers a generous dietary, though a patient in a London hospital would think this a starvation allowance. Probably also the difficulty in securing adequate ventilation of the wards was a considerable factor in the difficulty in securing normal healing of wounds in winter. A temperature of

50° or 60° below freezing point does not encourage the ward sister to open the windows. The lowest temperature we experienced was 67½° below freezing point (Fahrenheit) —that is, —30° Réaumur.

XVI. Frostbite and Trench Feet.

After our experience in the 1st and 4th London General Hospitals R.A.M.C.(T.) of frostbite and trench feet occurring in British, Colonial, and Belgian soldiers, we expected to meet with numerous examples of these troubles owing to the extreme cold of the Russian winter. To our astonishment, we saw far fewer cases than we encountered in the various London hospitals. The Russian soldier knows nothing about socks or stockings. He wraps his foot in a square piece of flannel and then puts on an excellent loose-fitting top-boot. Despite the fact that he has to face a temperature 30° to 40° lower than that encountered by his British comrade, he is far less liable to suffer from frostbite or trench feet. Admittedly he is more inured to extremes of cold, but as the result of our experience we recommend, as the best way to prevent frostbite and trench feet, a flannel wrap around the foot and a loosely-fitting top-boot.

XVII. Mortality.

On the question of the percentage of deaths we regret that, owing to the loss of many of our records, we can make no authoritative statement as to the exact percentage of deaths that occurred in our hospitals. It is, of course, obvious that no comparison can be made between the Petrograd base hospital and the field hospital in this respect. In the former institution we met with much the same type of case that finds its way into the big London general hospitals R.A.M.C.(T.), and the death-rate was low, certainly under 1 per cent., and probably nearer ½ per cent. The cases admitted into the field hospital were, naturally, in general, suffering from far graver injuries. The majority of them were not sent to us direct, but were transferred, by the courtesy of our Russian colleagues, from neighbouring hospitals for treatment because of the gravity of their injuries. Thus during our time at Cherukoff, with the sanction of the General of the Russian Red Cross, our admissions were confined to cases sent to us by the surgeons of the various Russian field hospitals, and every patient admitted was in a serious condition. W. D. H. can testify that during the time that he had charge of the field hospital the mortality was 4 per cent. Later on, as our hospital became better known and only the gravest cases were sent to us, it rose to nearly 5 per cent., the most frequent cause of death being gas gangrene.

A METHOD OF EARLY CLOSURE OF RECENT GUNSHOT WOUNDS.

BY

CAPTAIN WILSON H. HEY, F.R.C.S., R.A.M.C.(T.F.),

BRITISH EXPEDITIONARY FORCE;

HONORARY ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY.

EARLY closure of the gunshot wound has been for nearly three years the ambition of the surgeon and the pathologist, and although several methods have stood the tests of time and practice and have proved extraordinarily efficient, no apology is needed for making further suggestions. This paper is written to bring forward the use of a mechanical aid to excision of the wound—namely, the staining of the track of the missile, and, secondly, the use of a paste as the method of sterilization.

Excision of the Wound.

Ever since the possibility of an early closure of the wound was demonstrated by Gray and Carrel, it has been my custom in quiet times to examine and consider and operate on the wounds handed over to us in the casualty clearing station from the point of view of an early suture. In these later days the surgical organization of the armies has become so efficient that a surgical "push" in the old sense does not exist, and incisions of the fresh wound for the sole purpose of preventing spreading sepsis have been replaced for ever on the Western front by full and often final excisions. Hence this view now can be, and ought to

be, the universal one. And this outlook is the secret of success.

To the surgeon who so looks on the virgin wound which nature and the host are really anxious to close, asepsis is even more of a god than it was in his theatre at home. His operation is planned beforehand with the care and thought requisite for a possibly difficult procedure. The skin, on which rests the final visible proof of his good workmanship, is in the secondary suture preserved with the jealousy of the miser, and in a primary closure is removed with the thoroughness that eradicates rodent ulcer, so nice and so accurate becomes the generous but parsimonious balance. The incision is nowhere useless; its centre corresponds with the centre of the work, but as reckoned by ordinary war standards, it is almost appallingly long. Every part and pocket of the track is offered to his vision, and as his confidence in the certainty of early suture increases, so and at the same pace the number and length of his incisions grow and the exposure becomes automatically greater. Thought having been given to the blood supply cut off by the passing missile, the track disappears before the knife to a depth that is living and will live—it bleeds. Obstructing bridges of tissues are divided unhesitatingly with this knowledge of quick reunion, and the old operation of "removal of the foreign body" develops into an operation of some magnitude. The missile and the clothing come away buried in the tissues which surround them. Haemorrhage is arrested with more thoroughness than of old, and the toilet is as fairly finished as if the operator himself had broken the undamaged skin. Then, and only then, will all be well. Even if suture be impossible, a greater saving of life and limb will result. This is grandiose but not impossibly Utopian; it is a practical everyday affair to the surgeon who steadily preserves that outlook.

Depth of excision has always been cultivated, and after excising wounds in the usual way for nearly two years I attempted to stain the track. Since that first attempt, I have been of the opinion that formerly a complete surface excision of a deep and complicated muscle wound must have been for me a rare and happy event. Of course, by reason of important structures and the impossibility of invariably staining the whole track, complete excision is often impracticable, but the staining makes a more thorough removal possible, and also it indicates the points to which simple mechanical cleansing must be more particularly directed. When staining has been thought unnecessary, the final results have become immediately worse. In every case it is a help. It is never a hindrance, and the time expended on the actual staining is negligible. Certainly the operation is somewhat more prolonged, because the stain insists on a more thorough surface excision, and consequently multiple wounds demand multiple surgeons. At first I used a 1 per cent. watery solution of methylene blue, but later a ½ per cent. watery solution of brilliant green, for the sake of uniformity of material and its antiseptic action.

Wound Sterilization.

After complete excision, the problem resolves itself into the sterilization of a freshly infected surface. Here the first question was that of the antiseptic. Almost all available were tried, but the work of the Middlesex School in showing its peculiar antiseptic properties, its particular selective potency over the special organisms found in these war wounds, and more especially its fulfilment of practical requirements, has made me give whole-hearted support to brilliant green. But this is not all. I found that instillation of a watery solution of brilliant green through Carrel's tubes in wounds possibly incompletely excised sometimes resulted in a thin creamy yellow pus containing cocci; at this stage brilliant green, however applied, did no good; strong or weak solutions would neither sterilize nor affect the stationary condition of the wound. Dakin's solution, eusol, and other antiseptics would clear this up, suggesting the false inference that brilliant green was of inferior potency; and the simplest and one of the most effective of these complementary antiseptics was boric acid. And this might suggest that antiseptics suitably combined according to their predilection for the special organisms to be attacked might be of more value than the single antiseptic on which we commonly rely. However that may be, a combination of brilliant green and boric acid, suitably

applied, has proved of greater service than brilliant green alone. As has been stated by Webb, solutions of this dye give excellent results in the Carrel method of treatment. Solutions of the same strength by weight of brilliant green frequently possess different intensities of colour, and clinically it would appear that the antiseptic value varies with this intensity and not with the actual strength by weight.

Now the main principles of the sterilization of the wound are that the surfaces of the cavity shall be kept apart until the antiseptic has done its work, otherwise organisms will be imprisoned and spreading sepsis result; secondly, that fresh infections from without shall be impossible; and, lastly, that the local condition of the wounded part and the general condition of the patient shall be improved by providing rest in every sense of the word. And my second argument is that an adhesive preparation, which could be everywhere applied under an anaesthetic, which could remain active until the wound was sterile, and which could be removed when the wound was ready for suture, would best fulfil these requirements. Such a method reduces dressings to a minimum; the work of the medical officers, sisters, and orderlies can be diverted from the wards to the theatre, where all effort and assistance can be concentrated in the endeavour to make the first operation the last operation. The avoidance of dressings in the ward removes opportunities for daily reinfection, and early suture of the wound excludes it. Wounds are exposed for the purpose of diagnosis, rarely for treatment. As an ordinary example, with the paste to be described, a compound fracture of the humerus was looked at four times in four weeks—namely, at the operation of excision, on the fourth day for a smear count, on the fifth day at the operation of suture, and on the sixteenth day for the removal of sutures. The avoidance of pain and fear is no small matter.

A paste which would adhere to the freshly cut tissues in the presence of blood and effusion and which could be so prepared as to disappear in a given number of days, like hardened catgut, or which could be dissolved or removed at the operation of suture was required. But this healing balm has yet to be found.

Two years ago, and again later, amongst other methods I had worked at what I called the method of distension, which I will briefly relate simply as a blind alley of work. Here, after excision, the wound was primarily closed and the cavity made water-tight with two controlled inlet and outlet tubes. The wound surfaces were kept apart by light distension with various antiseptic fluid preparations until a normal temperature and pulse were reached, generally in a few days, when the tubes were removed and the sterilized surfaces fell into apposition. This primary suture was fascinating and was successful in primary amputations, excisions of joints, and in some fractures, but I discarded it because it was not safe, as no primary suture of a possibly highly infected wound can be.

The mucilages of tragacanth and acacia and gelatine had here been tried, but they would not adhere to the tissues satisfactorily for a sufficiently long period. Then Morison's bipp came into use and provided us with the best application we had seen. The results were startling, but it could be used only in small quantities on account of its poisonous effects; when very freely applied, blue lines on the gums, rapid pulses and high temperatures were not uncommon. Also slow or non-union of the skin edges was troublesome; this is commonly attributed to the liquid paraffin, but by altering its constituents it can easily be shown that the insoluble bismuth is the chief factor in producing this tardy union. However, bipp provided the requisites for the quality of adhesion—namely, the combination of an oily fluid and an amorphous powder. Experimentally, mixtures of the contents of the dispensary of a casualty clearing station and compounds obtained elsewhere were tested on raw beef in moving water, and in other ways, but nothing perfectly satisfactory has been reached. The media tried in actual practice have been varying mixtures of animal fats, suet, the hard and soft paraffins and soaps to produce pastes with requisite melting points, starches prepared in various ways, repetitions of the old mucilages, the heavy and light magnesias, calcium lactate and ordinary French chalk, liquid paraffin, olive oil and glycerin. None have been actually harmful; some could not be worked into the tissues, others remained unaffected in the tissues and could not be completely removed, and their

presence delayed healing, and others were absorbed too rapidly; none fulfilled all the requirements in the fresh wound, and, with the exception of the last five, they were definitely useless for the purpose.

Liquid paraffin and French chalk were most suitable, but, the latter being insoluble, a minimum quantity to make the paste adhere in the presence of wound fluids was determined; and this small amount does not appear to have any deleterious effect.

If necessary, the liquid paraffin can be replaced by olive oil; glycerin calls out so much fluid that it is only suitable for wounds which can be immediately closed or very rapidly sterilized.

The following paste was therefore made and is now the only one in general use:

Boric acid	11 oz.
French chalk	1 oz.
Liquid paraffin	8 fl. oz.
Brilliant green	17½ gr.*

* That is, 1 in 500.

The boric acid and French chalk must first be intimately mixed in a mortar, then the liquid paraffin worked in, and finally the brilliant green dissolved in rectified spirit. Considerable time and energy are required to avoid a paste with many isolated masses of boric acid. It is kept in jars and used chiefly from large syringes with very wide nozzle apertures or from grease pumps. Departures from the quantities and constituents of this paste have been invariably productive of worse results. If the chalk is omitted it will not adhere to any but the driest and freshest of wounds, and intimate adhesion to the tissues is an essential quality of a paste. No toxic effects have been observed.

TECHNIQUE.

Primary Operation.

After sterilization of the skin every endeavour is made to cover the wound track or surface with a one-half per cent. watery solution of brilliant green. In the case of a track this is done by injecting the dye through a metal or rubber tube of fine calibre, closed at one end like a Carrel's tube, and perforated by very many of the finest holes, so as to act as a spray; at the distal end are two rather larger holes to permit freer exit of the fluid. Tubes perforated for a distance of two, four, and six inches are used. A tube perforated for a suitable length is passed along the wound track, if possible up to the foreign body or fracture. The staining solution is then injected along the tube without force, so as to avoid opening cellular planes. Movement of the limb assists the insertion of the tube, and movement of the tube helps to a complete staining.

In the case of a surface wound, the syringe and occasionally gauze soaked in the fluid are used. At least two minutes should elapse before the excess dye is wiped away. Haemorrhage prevents staining.

The wound is then excised, using the stain as a guide. If a secondary suture is intended, only the damaged tags and a film of skin are removed, more will be cut away at a later date. Wide exposure and good visibility are essential for the removal of every particle of stained tissue; one or two incisions, each eight or nine inches long, are frequently required in a fractured femur. The excision proceeds systematically from the skin to the missile, which is removed last, preferably enclosed in its enveloping tissues. Irremovable structures are cleaned, and dirty bone is gouged. Only dry swabs or gauze soaked in spirit are used. A most scrupulous and exacting search for all bleeding points is essential.

The wound is dried throughout with spirit or 1 per cent. picric acid in spirit, and the paste is then rubbed into the tissues with all thoroughness into every recess. Five minutes may be so spent in extensive wounds. The syringe or pump is used to bring the paste to all deeper parts before rubbing it in, and later to fill the cavity to the brim. The deepest parts are treated first. Bone fracture areas are packed with it. Sutures may be inserted to bring together the skin edges which have been divided by the knife; with increasing experience more and more partial and complete primary sutures are done. Dry gauze dressing and firm bandages are applied, and splints are freely used.

After-Treatment.

Where the case progresses favourably—that is, where the temperature and pulse are descending, pain is slight or absent, and the patient is eating and sleeping well—the wound is not examined until the patient's general and local conditions suggest that the wound may be closed; in wounds of the soft parts this usually occurs on the third to the fifth day. It is impossible to give any rule as to the time for suture. Smear counts have generally been taken, and average reports of 0.2 to 2 organisms per field have been received. On the other hand, wounds with a greater number per field, even up to 9, have been intentionally and successfully sutured. It is really unnecessary to wait until the evening temperature is normal, but it is safer, and it is our usual practice. The clinical aspect of the wound and the patient's general condition are the best guides; in a patient possessing a sense of general well-being and local comfort, a normal pulse and temperature, a good appetite, and a good sleeping capacity, the wound, although glazed and green with the paste, but otherwise of good appearance and with no swelling, may be safely sutured; and experience shows that all of these requirements are not necessary. In a dubious wound or a fracture, smear counts are always made, and with cocci over four, or *Bacillus perfringens* anywhere, the case is left. If for any reason suturing is inadvisable and the paste originally put in has disappeared, the wound is repasted.

Where the case progresses unfavourably, the excision or the pasting has been incomplete, and repasting or further operative measures are required. Nitrous oxide anaesthesia is occasionally used for deep repastings in the ward. Refilling with paste and hot fomentations are frequently sufficient, as the temperature and pulse may be slow in coming down although there is no sepsis.

The Suture of the Wound.

Under an anaesthetic the wound is gently wiped out, dried with spirit, and the skin edges freshened or further excised. A very thin film of paste is then everywhere rubbed in and the excess removed. Silkworm-gut sutures are used for the skin. Closure of the cavity, preferably by underrunning gut or occasionally buried catgut sutures, is of great importance. There should be no tension on the skin; undermining followed by pasting can be safely done. Deeply running sutures have fine rubber tubes threaded on them. No drain is used with the exception of a minute one in a few fractures.

Primary Suture.

This is always done after pasting, where the wound has been completely excised without the blade of the knife entering the original wound cavity. It is frequently done in other cases and even in some minor bone injuries, but only experience with this paste can indicate the suitable ones; here the wound is filled with paste and only lightly sutured or else a very temporary drain is inserted. Primary suture will always be less safe than secondary suture, and the gain of two or three days and the avoidance of a short anaesthesia is not commensurate with the risks run in a case of the slightest doubt.

Abdominal incisions, head wounds, excisions of joints and other relatively clean wounds are pasted lightly in the absence of, and heavily packed in the presence of, a remaining cavity, followed by partial or complete primary suture as the case indicates.

All amputations in which flaps have been fashioned are filled with paste, particular attention being directed to the bone, and the flaps are apposed by two or three sutures; the closure is completed after wiping and slight repasting two or three days later when the pulse and temperature are normal. Flapless amputations are performed only in certain cases of gas gangrene or of extreme collapse.

RESULTS.

I shall not give any records; the staining and the paste are matters for trial by the individual surgeon. A strong, firm scar rapidly results; the skin unites well over a cavity such as is left by a pulped tibia. Extensive wounds of the buttock, and wounds complicated by division of large arteries or by fracture of any of the long bones, have been quickly closed. Fractures have been successfully sutured in three to five days, and wounds dividing muscle have been closed by partial primary suture with safety, which must be the outstanding feature of any method.

After the Carrel-Dakin treatment of any wound secondary suture can be safely and successfully performed at an earlier date and in the presence of a higher average field count if this paste is used.

It has also been packed into acutely inflamed cavities, such as in acute suppurative arthritis of the knee, with excellent results, but this has not been sufficiently tested to warrant a definite expression of opinion.

Where the foreign body has not been removed, I believe that pastes ought not to be used.

In conclusion, the case for complete excision must be again pleaded; it should begin and end all discussions on the wounds of war; without it, good antiseptics and this medley of pastes are almost useless in quickly healing the broken skin. Many good methods of sterilization have been doomed for want of it; a good paste will cover a multitude of sins, but ultimately the omissions will surely be found out. The pathologist has provided and is providing us with the means of sterilization, and now it rests solely with the surgeon as to whether the compound fracture shall become sterile in a few days or pass through months of continued suppuration.

My thanks go out to our consulting surgeons for their help and stimulation, to our pathologists and medical officers for innumerable suggestions in this and other work, and to the sisters for assistance in many practical details.

THE SPREAD OF INFECTION IN OPEN BONE, AND ITS BEARING ON THE TREATMENT OF PROJECTILE FRACTURE.

(Preliminary Communication.)

BY

E. K. MARTIN, MAJOR R.A.M.C.,

SENIOR SURGICAL REGISTRAR, UNIVERSITY COLLEGE HOSPITAL,
LONDON.

AND

G. F. PETRIE, CAPTAIN R.A.M.C.,

ASSISTANT BACTERIOLOGIST, THE LISTER INSTITUTE OF PREVENTIVE
MEDICINE, LONDON.

This paper gives a brief review of certain features in the spread of infection through fractured bones, which we have observed when studying this problem at a base hospital in France.

Our methods of laboratory work and the precise details of our observations will be fully described elsewhere. Here it will be enough to say that the material used was chiefly obtained from freshly amputated limbs. The injury to the bone was accurately mapped out up to the furthestmost fissuring, and the spread of bacterial infection along the bone was ascertained by cutting the latter into series of sections, and taking cultures from samples gouged out at each level in succession. Blood cultures were made from the patient at the same time so as to control the possibility of any general septicaemia that might be present, because the latter would have confused our attempt to analyse the local spread of the sepsis through the bone from the original wound.

When pathogenic organisms are implanted into normal bone from the blood stream pus is produced at the site of implantation, and so long as the bone remains closed they spread along lines determined by its anatomical conformation, produce further pus, and ultimately lead to necrosis. Before the war the description of these processes and of the subsequent course of repair made up the bulk of the accessible information about the interaction of bacteria and bone.

It has long been a surgical platitude that if a bone in a condition of early acute osteomyelitis is opened up until normal looking bleeding marrow is reached, it will recover without incident beyond the separation of sequestra. In projectile fracture of the shaft of a long bone the wound itself establishes some drainage simultaneously with the introduction of the infective agent—that is, organisms are implanted on to the surface of a widely open marrow, and although the complexity of the cavity and rigidity of its walls renders perfect drainage of the bone wound an unrealizable ideal, yet the conditions on any given surface of exposed marrow are adequate to prevent that spread of the inflammatory process which leads to pus formation in a closed bone.

It is a rare experience to meet with acute spreading osteomyelitis in the early stages of projectile fracture. Pus is seldom found in the medullary cavity of a long bone, nor is it seen issuing from the end of a bone unless a fissure is present. In the latter case the pus comes from the walls of the fissure, and the assumption that the marrow is infected to any appreciable depth must, in the absence of deliberate investigation, remain a hypothesis.

On the other hand, wounded cancellous bone is, to superficial inspection, more liable to osteomyelitis than the shaft, but this appearance requires analysis before a valid comparison can be instituted.

In the first place, owing to the greater strength and elasticity of compact bone and to the tubular character of the shaft, portions of the latter broken off by a missile usually retain their vascular attachments through the periosteum and comparatively few fragments become entirely detached. The solid articular end composed of inelastic cancellous tissue is more liable to be broken up in such a way that fragments are left entirely without blood supply. Such isolated portions are readily attacked by organisms and, if not removed, become foul and necrotic.

In the second place, on account of the physical properties of cancellous bone, the surface of the fracture is always covered with a layer of debris consisting of pulverized trabeculae, dead marrow and blood clot, a culture medium highly favourable to the growth of organisms. The elasticity of compact bone, on the other hand, causes comminution of the shaft to take the form of multiple fissuring rather than of pulverization. By reason of this contrast infection of cancellous bone can best be understood through the study of the results of treatment of the fractured surface, while the process of infection of the shaft can be followed most easily in the evolution of an untreated fissure.

Fissures.

Fissures fall naturally into two categories, the open and the closed, each of which has a distinctive clinical history.

A *closed fissure* is one whose walls spring back into apposition as soon as the force of the blow is exhausted. On this account no dead space exists in which organisms can develop, and such a fissure unites without incident. Closed fissures occur only in compact bone. Two kinds are met with in association with projectile fracture—one due to the direct effect of the missile itself, in which case the fissure commences in the main fracture and ends blindly in the bone; and the other to the indirect effect of the fall or muscle twitch which follows the mechanical stimulus. In the latter case the fissure does not communicate at any point with the original bone wound, and it is apt to assume the spiral form associated with simple fracture. It is in fact a minor degree of the indirect complete fracture which not uncommonly accompanies incomplete direct fracture of a distant part of the bone, or occasionally may even be associated with a simple flesh wound of the limb.

Open fissures occur in both compact and cancellous bone. They start at the main fracture and at the other end open on the surface of the bone into either muscle or joint. They form, in fact, an integral part of the fracture and differ only slightly from it in their reaction to infection.

All fissures in cancellous bone behave as open fissures.

EXTENSION OF INFECTION ALONG OPEN FISSURES.

A fissure whose walls are not in contact with each other affords ample opportunity for the growth of any organisms which may be present in the wound, as it provides a cavity with rigid walls, full of blood clot and defiant of drainage. Its behaviour can be studied clinically in an infected fracture accompanied by fissuring, where the incisions for drainage have been confined to the region of complete solution of continuity. The fissure full of blood clot is, then, in communication at one end with the wound flora, and at the other end opens into either muscle or joint cavity.

Organisms grow along it from the point of primary infection, and, since lateral penetration of the bone by organisms and toxic absorption from the walls of the fissure are comparatively slight, the process of extension is not reflected to a noticeable extent in the temperature chart, pulse-rate, or general condition of the patient. As soon, however, as bacteria escape from the fissure into

adjacent muscle or joint cavity, the clinical picture changes to that associated with pocketing or the development of septic arthritis.

Spread along a Fissure.

The absolute rate of travel of organisms along a fissure can only be determined by the bacteriological examination of serial sections of bones removed by operation. From a clinical point of view estimates of the apparent rate of travel have also been founded on the appearance of infection in a joint at the far end of a fissure. This use of a joint as an indicator is probably fallacious, since it implies the assumption that no delay occurs at the breach in the synovial surface. Delay is known to occur in the case of anaerobes and the staphylococcus, and probably happens to a less degree in the case of the streptococcus, although the material available does not allow of precise statement with regard to this organism.

The process may be illustrated by three cases showing different stages in the life-history of a fissure.

In the first a fissure led into the shoulder-joint from an infected fracture of the surgical neck of the humerus. Serial sections at intervals of 0.5 cm. examined bacteriologically showed that after three days no organisms had grown along the fissure from the main fracture.

In the second case a shell splinter with its attached fragment of cloth was embedded in the lower end of the femur, and from its site a fissure ran up to open on the surface of the shaft 10 cm. above. When examined three days after infliction of the wound, pus had spread to a distance of 0.5 cm. from the edge of the shell fragment. Beyond this the fissure contained blood clot, which, to the naked eye, was fresh and normal in appearance. Bacteriological examination showed that streptococcus, staphylococcus, and anaerobes were present at a distance of 4 cm. from the edge of the purulent area.

In the third case a fissure 9 cm. long led down to the knee-joint from an infected fracture of the lower third of the femur. Between fifteen and seventeen days from infliction of the wound a streptococcus reached the joint, and when the limb was removed on the seventeenth day the fissure contained pus throughout its whole length from fracture to joint.

Fissures, then, offer an easy path by which infection can reach distant parts of a bone, and the organisms concerned may be regarded as growing in orderly progression parallel to and on the surface of the exposed bone from one end of the fissure to the other, or from the original site of implantation throughout all the ramifications of a comminuted fracture. In the latter their progress is often accelerated by an imperfectly drained muscle wound with its opportunities for multiplication and accumulation of a "head" of organisms.

Lateral Penetration.

Pari passu with this spread of infection parallel to the surface a second mechanism comes into play—namely, the direct growth of organisms into bone at right angles to the fractured surface. This mechanism we have named *penetration*, and have studied it by the bacteriological examination of serial sections of bone away from a fracture.

Since penetration depends primarily on the number of organisms presented to an open bony surface, it is best seen in fractures of the cancellous end of a long bone in which the original debris of crushed trabeculae, dead marrow and blood clot has been left undisturbed by surgical interference. Organisms are constantly found in such a bone, and may extend to a depth of 10 cm. or more beneath the surface. This penetration of open bone by bacteria does not appear to be influenced by the particular bone affected nor by its structural variety (cancellous or medullary), nor again by the extent to which it is bruised. Open fissures, like any other part of a fracture, allow penetration to occur at right angles to their walls, and through their agency the degree of mechanical injury of a bone is reflected in the extent of the infection of its substance.

Penetration is influenced by the following factors:

1. Surgical treatment of bone and flesh wound.
2. Diminution of blood supply to the bone.
3. Types of bacteria.
4. Time.

Surgical Treatment of Bone and Flesh Wound.

However freely the flesh wound is opened up, penetration goes on unchecked so long as the original layer of necrotic debris remains on the surface of the fracture. If

this débris is removed by gouge or curette, and firm though bruised bone left at the bottom of a freely-excised flesh wound, penetration either does not occur at all or is limited to the surface layers of the bone.

The simplest conditions under which penetration can be studied are those obtaining in a flapless amputation stump, where bone injury and sepsis of soft parts are alike minimal. If such a bone be examined by the method of serial section organisms are found limited to the terminal 1 or 2 cm. The infected bone is softened, and probably represents the area of terminal necrosis which is so frequently found at a later date. Such an amputation stump affords direct drainage of both bone and flesh wound, and may be taken as a type, departure from which is initiated by deficiency of drainage of either bone or soft parts.

Direct drainage of bone with indirect drainage of the flesh wound are the conditions present after resection of a joint for suppurative arthritis, and these may be illustrated by four cases of resection of the knee-joint following projectile wound.

In two cases the failure of the operation to control septic absorption rendered amputation necessary. In these two cases organisms penetrated 9.5 cm. and 0.8 cm. into the tibia from the cut end in six and fourteen days respectively. In the other two cases the progress of septic absorption was at once arrested by resection and the patients were transferred to England with their wounds reduced to sinuses. Eight months later Captain Everidge, R.A.M.C.T., reported that the wounds had healed rapidly and that no recrudescence of sepsis had taken place, but that the ends of the bones were in a condition of rarefying osteitis and had not united. A tentative suggestion may, therefore, be put forward that penetration by organisms represents one phase in the development of rarefying osteitis.

That direct drainage of bone plays a part in the substitution of the latter process for that of suppurative osteomyelitis is suggested by a case in which a comminution of the upper end of the ulna and a minor fracture of the articular surface of the humerus were associated with a staphylococcus infection of the elbow-joint.

At the first operation, two days after infliction of the wound, the upper ends of both forearm bones were resected and the small gutter fracture of the humerus curetted. This was followed clinically by cessation of sepsis in the forearm, with extension in the upper arm. At amputation, sixteen days later, suppurative osteomyelitis was present throughout the lower third of the humerus, while the forearm bones were normal to naked-eye inspection, though serial sections demonstrated the presence of organisms to a depth of 3 cm. from the open ends. The staphylococcus was the only organism present in all cultures.

In this case, then, three open bones communicated with a common septic cavity, and although too much stress cannot be laid on an isolated instance, the penetration by organisms of all three associated with osteomyelitis only in that bone which was imperfectly drained is a suggestive comment on the different course taken by infection in open and closed bone.

Reinforcement of bone infection from an imperfectly drained flesh wound leads to an increase of penetration. This is seen in a fracture of the articular end of the femur, where the infected knee-joint lies across the track leading from bone to surface. In one such case examined a similar fracture of the upper end of the tibia was present in the same limb. The tibial fracture was exposed in the wound—that is, the element of soft part sepsis was negligible, and in association with this, organisms were confined to the surface of the bone. In the femoral wound, on the other hand, where reinforcement of sepsis from the infected joint took place, penetration occurred to a depth of at least 2.8 cm., the organism in each case being a streptococcus.

Diminution of Blood Supply to the Bone.

The importance of this factor can scarcely be overstated, for penetration seems to be directly proportional to the degree of diminution. It frequently determines amputation, and, while its effects are seen chiefly in an increased growth of anaërobcs (as in the soft parts), it also accelerates the progress of the streptococcus.

From the clinical point of view, the significance of this factor can best be illustrated by examples of interruption of the chief artery to the bone and of the medullary artery. Of two cases of projectile fracture of the os

calcis, comparable as regards degree of injury, duration of sepsis, and types of bacteria (anaërobcs) present, the posterior tibial artery was intact in one, divided in the other. In the former, penetration reached only 0.5 cm. from the surface of the fracture, in the latter, organisms were present throughout the whole bone. Again, from a fracture of the tibia below the entry of the medullary artery penetration extended to 1.5 cm. in the upper fragment, the blood supply of which was intact, and to 5.5 cm. in the lower fragment, from which the medullary artery was cut off.

Other examples could be quoted, but these are sufficient to indicate the paramount importance of an intact blood supply in enabling bone to resist infection, and the value of conservatism in the treatment of vessels during operative interference with infected fractures.

Types of Bacteria.

The chief groups of bacteria isolated from the bones examined were, in order of frequency:

Streptococcus	34 per cent.
Staphylococcus	23 "
Anaërobcs	23 "
<i>B. coli</i>	20 "

The average depth of penetration from the surface of bones with intact blood supply was:

Streptococcus	2.0 cm. in 10 cases.
Staphylococcus	1.5 cm. in 6 "
Anaërobcs	0.8 cm. in 6 "
<i>B. coli</i>	0.7 cm. in 3 "

Bones with heavy mixed infection are excluded from the above table.

Time.

While the influence on penetration of the duration of sepsis between infliction of the wound and examination of the bone is not easy to dissociate from other factors, the following two generalizations can be made from the cases examined:

First, within the first four weeks from infliction of a wound the continued presence of organisms on the surface of a fracture does not necessarily lead to infection of the deeper layers of the bone.

Secondly, the rate of penetration is at its maximum during the first few days, to the extent that the average depth of penetration during the first week is equal to the average additional penetration during the succeeding four weeks.

CONCLUSIONS.

The following conclusions can be drawn with reference to the operative treatment of projectile fracture. Some are already well recognized, none are universally practised.

1. Soft parts killed by the direct effect of the missile require removal.

2. An infected fracture of the shaft of a long bone requires opening to the full extent of solution of continuity.

3. In infected fracture of cancellous bone the superficial débris of smashed trabeculae, etc., requires removal. Solid bruised bone is able to resist infection and may be left.

4. As penetration is at its maximum in the first few days early operation is essential, especially in fractures of cancellous bone involving joints.

5. Every artery directly or indirectly supplying a fractured bone is of importance in the defence against infection.

6. In the presence of vascular injury proximal to the fracture, radical measures, such as amputation or resection of a joint, may be adopted with less hesitation.

THE Manor House Military Orthopaedic Hospital, Golders Green, was opened by Sir William Robertson, Chief of the Imperial General Staff, on September 29th. It has been founded by the Allies Hospital Benevolent Society, with the approval of the War Office and the assistance of the Joint Committee of the British Red Cross Society and the Order of St. John. The house, surrounded by nine acres of well-wooded ground and meadow land, is used as the administrative block, with which the wards, each containing forty beds, are connected by covered ways. Electrotherapeutic and hydrotherapeutic departments have been established as well as curative workshops. The accommodation at present provided is for 120 men, but it can be extended if necessary so as to provide 1,000 beds.

A METHOD FOR EFFICIENT DRAINAGE OF THE KNEE-JOINT.

BY

COLONEL A. W. MAYO-ROBSON, C.V.O., C.B., A.M.S.,
CONSULTING SURGEON, SOUTHERN COMMAND.

It will be generally conceded that, whether in civil or military practice, septic inflammation of the knee-joint is one of the most serious and anxious conditions that the surgeon can be called on to treat, involving as it does dangers both to limb and life.

The chief danger arises from the character and shape of the knee-joint with its various recesses and pouches, rendering efficient drainage in the ordinary position absolutely impossible.

With the limb in the usual dorsal position, the deepest part of the synovial cavity is in front of the popliteal space, much below the level of the suprapatellar pouch. Drainage is at present practically always effected by inserting a tube or tubes into the pouch above the patella, leaving much of the septic contents of the joint behind and between the femur and tibia with a tendency to make a way for itself to the surface by burrowing backwards into the popliteal space or along the course of the tendons in that region, upwards into the thigh, and downwards into the leg, or in both directions; this at the same time leads to septic absorption and blood poisoning from the imperfectly evacuated joint. Thus, in order to save life, the limb or the joint has not infrequently to be sacrificed.

Now, by changing the position of the limb, it is possible to make the suprapatellar pouch the dependent part of the joint, when by the very simple operation of inserting a tube into the top of the pouch the whole joint can be completely evacuated and purified, and if this is done sufficiently early, a speedy recovery may be anticipated with the joint mobility unimpaired.

Two changes of position will make the suprapatellar pouch dependent:

(a) The vertical position of the limb at right angles to the body with the patient in the dorsal decubitus, or

(b) The prone position of the body with the foot of the bed well raised.

In both positions the limb must be efficiently fixed on a splint, as fixation in inflammation of the knee-joint is only second in importance to drainage.

The first position can be easily maintained by a horizontal bar of wood arranged over the top of the bed, to which the limb is suspended by a pulley and weight. In this position dressings are easily carried out without moving the limb, and the pulley and weight enable the patient to be raised in bed for the use of the bedpan without pain or disturbance of the joint or dressings.

If for any reason the vertical position is inconvenient or difficult to carry out, the prone position can be adopted, the foot of the bed being raised and the limb slung from above by pulleys and weights for the thigh and leg.

This position also makes the suprapatellar pouch the dependent part of the articulation, and enables the joint to be completely evacuated of its fluid contents through a tube inserted a little way into that pouch.

As the prone position is irksome if prolonged, the patient, when once the joint has been emptied, may, if necessary, be turned on to his back, and the prone position adopted for from half an hour to an hour every four hours at first, and later about three times in the day, until the drain can be dispensed with.

When once the joint has been thoroughly evacuated of its septic contents, and if needful gently washed out with warm normal saline solution, the synovial membrane of the knee, like the peritoneum, is capable of taking care of itself. Long-continued drainage is very seldom required, and usually a movable joint will be obtained.

THE Minister of Munitions has added acetic acid of all strengths to the war material to which Regulation 30 A of the Defence of the Realm Regulations applies. Inquiries regarding this order should be addressed to the Director, Chemical Section, Trench Warfare Supply Department, St. Ermin's Hotel, Westminster, S.W.1.

FIVE HUNDRED CONSECUTIVE CASES OF ACUTE GONORRHOEA TREATED WITH VACCINES;

AND

A NOTE ON THE ELECTRO-CHEMICAL METHOD.

BY

N. P. L. LUMB, CAPTAIN R.A.M.C.

AFTER treating a large number of cases of gonorrhoea, it seemed that the only way of eradicating the disease was to attack it through the blood, in the same way as with salvarsan in syphilis. The administration of many thousand injections of a particular stock vaccine (Staphgon) prepared at this hospital brought to light one most encouraging fact, namely, the appearance of a visible discharge from the urethra or signs in the urine shortly after the injection of a moderate dose when the cure was not complete, or in other words, when the patient was not free from active gonorrhoea. This is referred to in Colonel Harrison's manual on the subject as one test of cure, and in my experience it has proved very valuable.

The return of the discharge can only be due to gonococci reappearing at the surface of the urethral mucous membrane, and it is reasonable to suppose that the vaccine has reached them through the blood stream, rendered them uncomfortable, so causing their migration from the deeper tissues to the surface. This, then, is a means of attacking the gonococci through the blood stream in the acute stage of the disease, and of penetrating tissues which the irrigating fluid cannot reach. By giving suitable doses of vaccine the hostility of the blood is increased to a maximum, whilst irrigation washes away the inflammatory products. The administration of a vaccine as a routine form of treatment in the acute stage of gonorrhoea has not up to the present been generally adopted, and I have thought it worth while to bring the results to notice. Both in regard to dosage and the period of time between successive injections experimental evidence had to be accumulated, and the effect produced by varying these two factors was observed in several hundred cases before finally deciding in favour of the method now to be described, which differs considerably from that usually adopted in the chronic stage.

REPORT ON FIRST FIFTY CASES.

The results of the first series of fifty consecutive cases are quoted below. Most of the cases to be dealt with have been severe, and owing to the circumstances in which the disease has been contracted, the patients have not reported until obliged to do so. In nearly every case there has been a discharge for at least a week before any local treatment has been commenced, and the disease consequently well established. Briefly, the pathological condition in such cases is that the gonococci have invaded the greater part of the urethra and are no longer on the surface alone, whence they can be washed out by an irrigating fluid, but have penetrated the mucous membrane and lie below the surface, as well as in the glands of Littre and the various lacunae. Once this has occurred it becomes a matter of much greater difficulty to eradicate the disease, for the irrigating fluids merely wash away the accumulated discharge and do not penetrate into these side-channels of the urethra, within which the organisms remain indefinitely. The discharge may disappear entirely under ordinary conditions of living, only to return if the patient take a considerable amount of exercise or indulge in alcohol. This is due to a reinfection of the urethra by gonococci from these glands.

The rationale of the method described is as follows:

1. To affect the blood as early as possible, with a view to

- a. Antagonizing the gonococcus,
- b. Diminishing the likelihood of complications.

2. To get as big an action as possible in the shortest time without inducing a negative phase.

It has been proved by the work of Eyre and Stewart and others that a gonococcal vaccine increases the power of the blood to destroy the living organisms, and that one positive phase can be superimposed upon another by giving suitable injections at the proper intervals, thereby obtaining the maximum effects.

In utilizing this fact two main lines of treatment were adopted:

1. Intensive dosage with a mixed stock vaccine (Staphogon) containing 20 million gonococci and 50 million staphylococci per c.cm.

2. Weak irrigations on Janet's system.

I have called the dosage intensive because the amounts given are considerably larger and the intervals between them considerably shorter than has hitherto been the case in vaccine therapy. Three injections are given within the first five days, the total number of gonococci injected in that period being 60 million and 150 million staphylococci. It is believed that by adhering to this scheme a series of positive phases is actually imposed one upon the other, thus producing the maximum effect.

Irrigation is commenced with a weak solution of potassium permanganate (1 in 8,000) and then replaced by 1 in 6,000. This strength is not exceeded without special reason. In all but a few cases it is found to be sufficiently strong, and, whilst washing out the urethra efficiently, it neither irritates nor injures the mucous membrane.

Method.

On the first morning after admission a two-glass urine test is made, the urine of six or seven hours being passed into two conical glasses on rising in the morning. About four ounces are passed into one glass and the remainder of the bladder contents into the second one. The patient stays in bed for the first three days, getting up only to irrigate in the morning and again in the afternoon. Milk diet is ordered and an unlimited quantity of barley water allowed. Aperients are given regularly as necessary to keep the bowels freely open. Irrigation is commenced with 1 in 8,000 potassium permanganate on Janet's system, the container being placed 5 ft. above the patient, who is instructed to thoroughly wash out the anterior urethra first and then to get the solution into the bladder. A dose of 5 million gonococci is given on the first morning, and urotropine, according to the following formula, for five days.

R. Urotropine...	gr. x
Aq.	ad 3j
R. Ac. sod. phosphat.	gr. xx
Potass. citrat.	gr. x
Syr. aurant.	3 ss.
Inf. buchu	ad 3j

Dose: One ounce of each, mixed just before taking, three times a day.

On the second day irrigation is carried out morning and afternoon as before, and the vaccine is given again on the third morning, the dose being 10 million. By the fourth day the discharge in most acute cases has diminished to a small drop and the patient is allowed to get up and go about as usual, taking a moderate amount of exercise. He now irrigates with 1 in 6,000 potassium permanganate and the diet becomes an ordinary one, except that fish or a small quantity of meat is allowed, alcohol and condiments being forbidden. On the morning after getting up a four-glass urine test is made and used as the guide in further treatment. On the fifth day the medicine is stopped and another dose (50 million) of gonococci given, irrigation being continued as before. The patient then passes a two-glass urine test, as already described, on alternate days and the treatment is modified as considered necessary. On the ninth day he receives a second dose of 50 million gonococci, and a bougie is passed on the tenth day, the urethra being massaged if the glands are involved. The bougie at this stage is valuable in three ways:

1. It allows the massage of Littre's glands.
2. It reveals any tendency to stricture.
3. It has a stimulating effect on the mucous membrane.

On the thirteenth day a third dose of 50 million is given, and by the sixteenth day, when it is again repeated, the discharge has almost invariably ceased. The urine in both glasses is clear, though the first one may still contain a few flakes. The patient at this stage is taking as much exercise as possible, playing games every afternoon and eating a full diet. If under these conditions no discharge be apparent, the irrigation is changed to 1 in 1,000 zinc sulphate or 1 in 4,000 zinc permanganate for two or three days, and then all treatment stopped. The urine is examined as before and a final dose of 50 million gonococci given two or three days after all treatment has ceased. If the patient be not free from active gonorrhoea, this "provocative" dose invariably gives rise to signs in the urine, or an obvious discharge, within twenty-four hours, and this is a most valuable test. If the urine remain clear after this, the case is watched for another three days and then considered clear.

Results.

In the first series of 50 cases so treated 37 have been discharged with an average duration of twenty-two days in hospital (that is 74 per cent.). Of the remaining 13, 6 were complicated by pus in the prostate and one with epididymitis

A certain proportion (13 out of 50, that is, 26 per cent. in the series) do not clear up in so short a time. This is what one would expect and is generally due to one of the common complications. Epididymitis and prostatitis accounted for 7 out of the 13 in the series. In these the complications are treated on the usual lines, vaccine treatment being continued. In some other cases doses of 100 million have been given at this stage with very satisfactory results. In all the complications of gonorrhoea this vaccine has given equally good results, and but a small proportion of early cases, treated with it from the time of admission, have developed prostatitis or epididymitis.

Epididymitis.—A large number of cases develop this condition before admission, but the testicle rapidly becomes normal under local treatment combined with vaccines. Two or three patients who had suffered from the same trouble in years gone by spontaneously remarked that the testicle which had always remained enlarged had, since the vaccine, assumed its normal size. The average duration of the first 11 cases treated on this plan was twenty-four days.

Periurethral Abscess.—In this condition the vaccine has proved of considerable value in helping to free the enlarged and infected glands from discharge and, at the same time, reducing the infiltration along the whole urethra which so frequently renders it like an atheromatous artery in consistence.

Arthritis.—Excellent results have been obtained. Four acute cases have been treated and all have recovered with perfect movement. One of them, who was unable to stand, was affected in the hips, knees, and ankles. He left hospital after seven weeks with perfect movement in every joint and was able to proceed direct to his unit at the front.

General Effects on the Patient.

These come under four main groups:

1. Mental relief at the rapid disappearance of the discharge.
2. Rapid disappearance of pain on micturition.
3. Rapid disappearance of pain on irrigation.
4. Exercise can be taken without delaying the cure.

The mental state of the gonorrhoea patient is very important, and anything which tends to turn his thoughts away from the site of the disease and associated ideas is valuable. The actual injections tend to do this, but far more valuable is the rapid diminution in discharge, which convinces the patient that he really is getting over the attack.

Pain on micturition and during irrigation speedily disappears, considerably increasing the patient's comfort, whilst he can lead an ordinary life and take plenty of exercise without delaying his recovery. No relapses have to be recorded so far, though nearly every case has returned direct to duty at the front.

REPORT ON FIVE HUNDRED CASES.

The foregoing report, prepared some months ago, contains the results of fifty consecutive cases treated with vaccines on the plan outlined therein. But with such a comparatively small number of cases no final decision was justifiable as to the value of the method, and it was decided to continue the investigation. Five hundred consecutive cases have now been collected, acute ones only being included, and in most of them ten to thirty days had elapsed before receiving any treatment. No selection was made and each case was added to the list on commencing treatment, any complications developed and the number of days under treatment being added on completion of attendance. The relapse rate was accurately available, because of the fact that all relapses were returned for readmission to the same hospital.

Revised Method.

A modification has been introduced in the dosage and also in the frequency of the injections, though the number of days between each remains the same. It was found that an initial dose of 50 million gonococci could be given without serious reaction, and double this dose on the third day; this plan was adopted throughout. On admission a dose of 1 c.cm. (50 million gonococci, 150 million staphylococci) is given, and 2 c.cm. on the third day. The third injection is given on the sixth day, the dose remaining the same, and a similar injection on the ninth day; two more doses of 2 c.cm. given on the twelfth and fifteenth days complete the first course. No further injections are then given for ten days. At the end of that period a second

course of six injections may be commenced, the dose remaining at 2 c.cm., and the interval between each injection being two clear days. Table I shows this in detail.

TABLE I.

<i>First Course:</i>			
First day	1 c.cm.*
Third day	2 c.cm.
Sixth day	2 c.cm.
Ninth day	2 c.cm.
Twelfth day	2 c.cm.
Fifteenth day	2 c.cm.
<i>Second Course:</i>			
Twenty-fifth day	2 c.cm.
Twenty-eighth day	2 c.cm.
Thirty-first day	2 c.cm.
Thirty-fourth day	2 c.cm.
Thirty-seventh day	2 c.cm.
Fortieth day	2 c.cm.

* = 50 million gonococci.

Many cases require one course only, others two, the latter particularly when complications are present. At the end of the first course of vaccines the two-glass urine test usually shows that the patient is practically free from discharge, apart from a little muco-purulent secretion in the morning. Irrigation is continued until nothing is seen at any time, even after vigorous exercise, and then stopped altogether. The test dose of vaccine (100 millions) is given, and the urine examined for six or seven days afterwards. If no discharge reappears the patient is considered to be clear. Owing to existing circumstances it has not been practicable to examine urethroscopically every patient before leaving hospital, but in a considerable number this was done. With regard to the second course, it should be made clear that the whole of the six injections are frequently not required. When the urine is free from flakes and no discharge is seen at any time, irrigation is stopped and the test dose of vaccine applied. Should a discharge reappear, indicating that the disease has not been eradicated, the remaining number of vaccines to complete the six is given, and then a second interval of ten days allowed to elapse. Irrigation and local treatment have been carried out in accordance with the original scheme.

Results.

The results of 500 consecutive cases are given in Table II with details of the different complications and the number of days under treatment. It will be seen that 222, or roughly 44 per cent. of the cases, were complicated. This is accounted for by two factors: (1) Active service; (2) lateness in reporting.

A patient contracting gonorrhoea often does not realize the condition until the discharge is profuse, and during that time a spell of hard work will do much harm. Also a number delay reporting to the medical officer in the hope that the discharge will disappear. Thus of 101 epididymitis cases in the series of 500 acute cases 70 were present on admission and 8 of the 10 arthritis cases. Of the prostatitis cases the exact number present on admission cannot be stated, since routine examination of the prostate was not carried out until the end of the second week of treatment.

An analysis of the uncomplicated cases shows that 60 per cent. were under treatment thirty days or less, with an average of nineteen days. The average duration for the whole of the uncomplicated cases (278) was thirty-five days, or five weeks.
